Fresh attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoograpicon. Each department increases daily, and the Pavillon performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

How to STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus, order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Gover Mining and Milling Company.

Principal place of business, San Francisco, California. Location of works, Amador county, near Drytown, California. Notice is hereby given that at a meeting of the Board of Trustees, held on Wednesday, the 6th day of August, 1879, an assessment (No. 33) of Fifty Cents per share was levied on the capital stock of the corporation, payable immediately, in gold coin or legal currency of the United States, to the Secretary, at the office of the company, Room 8, No. 402 Front street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Tuesday, the 29th day of September, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 6th day of October, 1879, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Trustees, W. O. WILSON, Secretary, Office, Room 8, No. 402 Front street, San Francisco, Ca.

Annual Meeting—Office of the Mono & Cross Consolidated Mining Co., San Francisco, Cal.

August 8th, 1879. The Annual Meeting of the Stockholders of the Mono & Cross Consolidated Mining Company, for the election of a Board of Trustees for the ensuing year, and for the transaction of such other business as may properly come before it, will be held at their office, Rooms 3 and 4, No. 300 California street, San Francisco, California, on Monday, August 26th, 1879, at two o'clock, P. M., of that day. Transfer books will be closed on Thursday, August 14th, 1879, at three o'clock, P. M. J. M. BUNTING, Secretary.

Annual Meeting—Safety Powder Co.

Notice is hereby given of the annual meeting of the stockholders of the Safety Powder Co., at their office, corner Octavia and Greenwich streets, on Saturday, the 30th day of August, 1879, at the hour of three o'clock, P. M. By order of the President, S. O. GREGORY, Secretary.

Lathe Without Saw Attachments.

Material eighteen inches long and eight inches in diameter can be turned upon it. The pieces that accompany this lathe without extra charge are two T resis, two planpenters, one spur center for wood turning, and one face plate.

Price of Lathe without Saw Attachments.....\$45. Price of Lathe with SCROLL Saw Attachment.....\$55.
 Price of Lathe with both Scroll and Circular Saws, \$70.

Trump Drill Chuck.

Chuck for drills 1/2 and under, Price.....\$1.60
 Chuck for drills 3/4 and under, Price.....\$2.25
 They are made on solid steel plug, centered and readily fitted to Lathe or Drill Press.
 SEND FOR CIRCULAR.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated. With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

Nos. 653 and 655 Mission Street, San Francisco, Cal.

EDWARD G. DENNISTON, - - - - PROPRIETOR.

Pioneer Plating Works.

MANUFACTORY OF

Silver Plated Amalgamating Plates,

For Quartz Mills and Gravel Claims. Are prepared to furnish any size Plate promptly and satisfaction guaranteed. Old Copper Plates purchased, Plated or the Gold Extracted by the most complete process, at small cost, and the copper saved.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Number 9.

The Prospector and His Rewards.

Every now and then there comes to us an enthusiastic prospector bringing what he believes to be samples of some mineral found by him in the course of his peregrinations over the country. Sometimes these samples prove to be what they are taken for and sometimes not. Sometimes they are the genuine article, but so debased through combination with other troublesome or worthless substances as to render them of no account. Again, the samples brought in may be genuine and pure enough and the mineral may exist at the place where found under highly favorable conditions in all save its remoteness or inaccessibility from points where it can be marketed or utilized. Between these several causes tending to deprive such discoveries of commercial value, there results to this worthy class of persons much disappointment.

The prospector before setting out has as a general thing some idea, but not a very definite one, as to how this, that or the other mineral ought to look, and noticing in his wanderings something that resembles it, he makes a halt and forthwith proceeds to make a more close examination. If, after taxing the scanty resources of his mineralogical lore and venturing a few intelligent guesses he is favorably impressed with the appearance of the thing, he selects the best looking pieces, and wrapping them carefully in such bits of rags or remnants of the MINING AND SCIENTIFIC PRESS as he may happen to have about him, loads his jack or other agent of transportation and proceeds on his journey unhesitatingly, to be sure, elated by the presumed importance of the discovery, he turns his footsteps directly homeward.

Arrived in San Francisco he is not long in seeking out his sanctum and making known his good luck, removing, meantime, from a well worn sack bits of rock, mineral, petrifications, and what not, picked up in some distant range of mountains or on the far-off desert. He has discovered this, that and the other mineral or metal exhibiting these specimens in evidence of his find. He has come across an ore-bearing vein of gold, silver, copper, etc., the like of which was never before seen, or it may be a mountain of coal, sulphur or salt—a mineral spring of marvelous medicinal virtues—an irreplaceable oil well—a soap mine, possessed of fearfully detergent properties—slabs of mica, fit for building a crystal palace—bundles of asbestos, the probable remains of an ancient Phoenix—bricks of Kaolin already molded and laid up in a huge kiln resembling the Tower of Babel, ready for burning—with more alike useful and wonderful. If our prospector be of a scientific turn of mind, he may have to tell us of the discovery of a live glacier, resting in some lofty cradle of the Sierra, and extinct volcano standing off in some out-of-the-way place—a strange petrification, likely a Digger Indian or a rattlesnake of the pliocene age, or other thing of especial interest to the curiosity hunter or the savant.

They are generally honest and very often highly intelligent, these professional prospectors, and despite their over-sanguine temperament and many mistakes, must be accounted a very useful class of citizens, the world being indebted to them for many of the most important mineral discoveries ever made. Like the frontiersman, the mountaineer and the trapper, they are the out-growth of circumstances—a necessity of the age; and being so useful and almost indispensable it is a pity they should so often be doomed to disappointment,—their sanguine expectations being blighted by the inevitable decrees of science. Happily, however, they are not the kind of men to be easily dis-

couraged. Being naturally enthusiastic and hopeful they never give up. If one trip to the mountains fails of reward they are ready to undertake another. They know of another good place to prospect, or have overlooked something that they would like to go back and examine, anyhow, and so they are ever kept on the tramp, these brave and hardy men, a light heart within and a hopeful future before them.

Change in the Mining Department of the University.

During the last vacation a change has been made in the instructions of the mining department of the University of California. Mr. Geo. Becker, who has for a number of years given all the special instruction to the mining students, resigned to accept a position on the United States Geological Survey. Having made this instruction a study for some time, and having directed the furnishing of the new building so

The Brown Caloric Engine.

For the past 50 years experiments have been tried in hot air, which proved the possibility of the use of that power, but the non-perfection of construction of the machines caused partly failures and partly limited results only. Mr. Felix Brown, after several years experimenting, finally brought out the engine shown in the engraving, one of which is on exhibition at the Mechanics' fair, by Parke & Lacy, Agents, 417 Market street.

In this machine, the heater, or furnace, is completely separated from the working cylinder, so that the former may easily be relined with fire bricks, should it become necessary. The packings are not exposed to heat. The inlet and outlet valves are operating independent of each other, so that any degree of expansion desired may be obtained. Noiseless motion and the facility of replenishing the furnace during

Resistance of Metals to Repeated Shocks.

About 12 years ago, the Prussian government directed Wohler to make a series of experiments upon the resistance of iron and steel to repeated stresses. The results of his experiments are known as Wohler's laws, which is described in Dr. J. J. Weyrauch's work on "Strength and Determination of Dimensions of Structures," translated by Dubois. "Rupture may be caused not only by a steady load which exceeds the carrying strength, but also by repeated applications of stresses, none of which are equal to the carrying strength. The differences of these stresses are measures of the disturbance of continuity, in so far as by their increase the minimum stress which is still necessary for rupture diminishes."

An illustration of this meaning of the first portion of this law is as follows: If 50,000 pounds once applied will just break a bar of iron or steel, a stress very much less than 50,000 pounds will break it if repeated sufficiently often. Repeated experiments have fully confirmed this law.

William Kent, in a paper before the American Institute of Mining Engineers, remarks upon this law, and regards as a fact that rupture may be caused by a succession of shocks or impacts, none of which alone would be sufficient to cause it. Wrought-iron will crystallize by repeated blows in service and become weaker than cast-iron. Iron axles, the piston rods of steam engines, and other pieces of metal subject to continuously repeated shocks invariably break after a certain length of service. In other words, the "life" of the metal is limited. Iron rods in bridges sometimes crystallize and break, although the rods in most of our iron bridges of to-day may have 5, 50, or 500 years of life yet allotted to them, due to their factors of safety.

It is well known that wrought-iron subjected to continuous vibration assumes a crystalline structure and its cohesive powers become much deteriorated, and here our knowledge stops. Mr. Kent thinks it probable that a similar law may hold true in regard to repeated shocks.

The investigation of this subject is attracting considerable attention, all the more since steel is replacing iron in many situations. In experiments made by Mr. William Metcalf in 1877 resulted in the knowledge that high carbon steel

THE BROWN CALORIC ENGINE.

recently erected for mining and mechanics, and, thus understanding its best managements, the institution loses in Mr. Becker a valuable aid.

As successor Mr. S. B. Christy, formerly an associate editor on the MINING AND SCIENTIFIC PRESS, has been appointed. Mr. Christy is a native Californian, has graduated in and grown up with the University. Since graduating, Mr. Christy has acted as instructor in qualitative chemistry, and has thus gained ample experience in the act of instructing. He has also employed a great deal of time in putting forward his special studies in metallurgy and higher mechanics, which will greatly aid him in his new position.

THE FLOODED MINES IN THE COMSTOCK.—Of late excellent progress has been made in draining the water from the flooded mines. The pumps are all working splendidly, and Aug. 27th there was but 35 feet of water (measuring on the slope, or 18 feet vertically) above the 2200 level. As they are now handling a certain amount of accumulated water they will have an easier task when they reach the 2200 level, and have to do with the regular influx only. Useless some unlooked-for accident shall occur it will not be long before the 2200 will be seen and the volume of water flowing into the mines at that point ascertained.

working hours without the cause of any delay are among the merits of the engine. The manufacturers state that the consumption of fuel is only from two and one-half to three pounds of coal per horse power per working hour. The construction of the engine is strong, all the bearing parts, journals, shafts, rods, etc., being made of cast steel, or case hardened. The engine is particularly useful as a motor for elevators or hoists.

SILVER.—The annual production of silver is estimated at \$80,000,000 in value, more than one-half of which is brought out of our mines. Of this amount not less than one-fourth enters into consumption in the mechanic arts. From a report made to the British Parliament, in 1876, we learn that in 1871, of the nations under the silver system, the populations aggregated 841,000,000; of the gold and silver system, 139,200,000; of the gold system, 85,720,000. At the time of the report (1876), the following changes had been wrought in the three systems: Populations under the silver system, 717,600,000; under the gold and silver system, 97,800,000; under the gold system, 247,720,000.

At Memphis new cases are occurring every day. Howard Association expenses are \$1,000 per day. All who can leave have fled.

was better adapted to resist repeated shocks and vibrations than low carbon steel. Further experiments are necessary, and in this view an apparatus has been contrived to test directly the relative resistance of metals to repeated shocks, and which, it is believed, will increase our knowledge upon the relative tensile strength of steel and wrought-iron in regard to resisting repeated shocks, and also as to the general changes that occur in the disturbance of cohesion. Possibly the influence of the chemical constituents may be ascertained and measured.

The piece to be tested is laid upon an anvil and supported by being fastened into a holder or sleeve. A revolving shaft raises and lets fall an annular weight upon the test piece. Sixty blows per minute may easily be given.

If one-half the information claimed for this testing machine can be obtained, it will practically accomplish a practical result which heretofore has been mere theory.

THE ZULU have finally been beaten, but Cetewayo keeps up the war single-handed. Sir Garnet Wolseley is straining every nerve to catch him.

It is rumored that Russia has ordered from American shipbuilders vessels to the value of 25,000,000 roubles.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Concrete as a Substitute for Stone in California.

EDITORS PRESS:—Artificial stone, or concrete, has been more or less used for ages, and the committee appointed by one of the scientific societies of London to examine the pyramids of Egypt, made so thorough an examination of the material composing those remarkable preservations of stone, that no doubt was left in their minds of the fact that they were concrete, or artificial productions; and the strongest proof of their being artificial was the fact that analysis showed them to be a silicate of lime, quite uncommon in that country, and finding large deposits of amorphous silicate, was forced to the conclusion that the obelisks that had stood the devouring tooth of time for so many centuries, was a silicate of lime produced by the association of the materials indigenous to that country. Through Mexico and Central America can be found the strongest evidences of the artificial production of stone built by a prehistoric race, and an examination of some of the ruins give unmistakable evidences of having been formed from a plastic etate; and if we reason from analogy, the proofs are conclusive that artificial stone can be made more durable than that which nature furnishes, for we know that the lofty mountain crumbles beneath the elements, and the reason is obvious: The natural etone, being more porous, admits the moisture and this subtle element insinuates itself into the body of the material, and particle after particle drops from the mass and the "mountain comes down to the valley." But not so with artificial etone; it is far more compact and less porous, presenting to the elements almost, if not quite, a perfect surface; for a good concrete is, or should be, quite impervious to water.

In the old country we now have vast aqueducts, bridges, viaducts, sea-walls and depots constructed of this material, and the strength and durability are beyond question, while their heavy and artistic finish are not equaled by any cut stone of the finest design.

Much experimenting has been done in the way of manufacturing a building etone, but did not prove a perfect success until the introduction of the Portland cement; but with the use of that, etones of any and all kinds have been made so successfully that the wonder is that they are not more extensively used.

After the great fire of Chicago several companies were organized and many buildings were erected that have proven to be not only permanent, but superior to the best brick. I find many of your sidewalks artistically laid with artificial etone, fitting accurately to all the irregularities of the location. A notable illustration can be seen around Gov. Stanford's residence. Although there are many places where it has proved quite as convenient and lasting, my purpose in writing this article is to call attention to the fact that no country in the world could use it to better advantage than our own State of California, as good material is abundant and the best cement in the world made at your very doors by the California Portland Cement Co., whose works are at Santa Cruz, and who can furnish any amount at the same price the imported article can be had for, and which will be found superior to the imported article. And as there is no freezing and thawing in this country to affect the stone until it becomes perfectly hard, it must necessarily be permanent, and experience has proved that in a uniform climate like that of California, the induration continues for a few years, until a perfect silicate of lime is formed; then the stone remains permanent, as the surface upon examination is found to be entirely free from pores, and consequently waterproof.

The writer has seen and examined a variety of articles at Chicago, that were so perfect in form and hardness that we were much surprised at the success attained in window caps and sills, doorsteps, brackets, cornices, eave-troughs, conductors, coping stone and fence foundations, cemetery ornaments of the most beautiful and artistic design, and so much cheaper than cut etone.

New methods of uniting sand, gravel and other materials into building blocks were freely explained and the result was more than satisfactory to those who have used them, and when the community becomes educated to the value of this mode of stone work it will be universally adopted at a great saving of expense and a more beautiful and permanent system of building.

One objection urged against brick or stone edifices in this city is the amount of moisture in the atmosphere arising from the fogs that come up from the ocean, rendering the houses damp and uncomfortable. This difficulty arises from the porosity of the material used in building, and continued dampness of the atmosphere at certain seasons of the year; and as solid walls are built, the moisture penetrates through the wall, making the house damp, but if concrete brick are used, such as are used in the Eastern

States, that are made hollow, and properly laid up they form a double wall, having an air space throughout the entire center, thus breaking up the effects of capillary attraction and leaving the inside wall always dry. In addition to this advantage the concrete is indurating from month to month and the sanitary condition of the building constantly improving, so that a perfect building could be secured by the use of this kind of material.

The crude material for making concrete is more abundant in this country than any that has ever come under the observation of this writer, and now that this important factor has been taken hold of and can be supplied in any quantity at a fair price (we mean California Portland cement), it is to be hoped that parties contemplating the erection of a fine residence will not lose sight of this cheap and substantial mode of building, for they will certainly secure a residence that will give a more uniform temperature than any other building that can be erected, and that will stand the climatic changes for centuries, for the writer has seen many evidences of the durability of this kind of material.

Its application need not be confined to the erection of buildings, but fence posts, hitching posts, stone steps, etc.; and in speaking of stone steps, we once saw a hollow stone step, the upper surface, where the largest amount of wear would be found, was two inches thick, while the rest of the block was only one inch and could be handled by two men easily; they had been in use for over four years, and their hardness was much greater than any native stone. The same party exhibited two gate posts that had been made on the ground and in position by forming them in a board mold, and quite a long line of fence posts after a similar manner, all in a perfect condition.

The enterprising gentleman had taken his formula from Musprat's Chemistry (so he told me) and had made some improvements that were not only lasting, but ornamental at a cheap rate. Others can imitate and be largely benefited. The following proportions will give good results: For pavements and curb stones, 30 parts of Portland cement; 50 parts of sharp, clean sand; 50 parts of gravel or finely broken etone, such as granite, bay salt or crystallized limestone—should be broken to the size of a pea; 50 parts of pulverized brick. The whole should be thoroughly mixed before adding the cement; and in the selection of the cement, ask for the slow-setting cement, as this enables you to make a larger batch at a time.

For fine work, such as fence posts and ornamental work, the following will be found to be suitable: 30 parts of cement (Portland); 50 parts of sand; 50 parts pulverized crystallized limestone, and the finer it is pulverized the smoother will be the work, as it has been demonstrated that the fine particles settle on the outside, making the work very smooth. If the posts are formed in position, as I have seen them done, then coarse fragments of stone can be pushed into the mold, care being taken not to allow the rough parts to project.

The above formula makes a fine chimney-top and can be colored to taste by a small percentage of ochre added to the mass while being mixed, and ochre containing oxide of iron, is beneficial in producing hardness and smoother surface. For the erection of houses a much coarser kind of material may be used, such as spare stone from the quarry, broken bricks, cobble stones, etc., and are used by making the cement mixture a little thinner and forcing the fragments into the mass while the form is still in position on the wall. And in a country where sand and stone can be had for hauling, the only ingredient to be bought will be the cement, and under these circumstances it is cheaper than wood at very common prices, and any person of ordinary skill can build his own house. In traveling through your State, I have seen locations where lumber was very high and stone on the ground in abundance, with a board shanty that would not keep the rain out cost five times as much as a comfortable house made of the material on the ground. And I lay these facts before your numerous readers that they may profit by it, for in hundreds of locations a few barrels of cement and a few days' work will insure any man a comfortable house to live in, and, in the hot weather of California, will be found to be always cool, and in wet weather always dry. Other formulas for specific work are common property and within the reach of any that desire to investigate it or put it into practical use.

It is a matter worthy the attention of any one contemplating a permanent improvement, and the writer will be pleased to give any further information to those who may desire to look into it, for having seen the most substantial benefits from its use in many ways, has no other purpose in view than laying it before the public as one of the improvements that science has clearly demonstrated for our economy and usefulness.

Experiments tried with the California Portland cement by the U. S. Engineer, Calvin Brown, Esq., and Governor Purdy, gave a result superior to anything attained by the imported article, and I refer to the fact because it reflects credit on our own citizens for taking up a matter like this and producing an article superior to any in the world; for all such enterprises should be publicly admitted and acknowledged, as they are a golden link in the prosperity of the State.

J. T. D.

[We are acquainted with the writer of the foregoing communication, and any inquiry concerning the matter may be directed to this office.—Eds. PRESS.]

Eureka and Its Mines.

EDITORS PRESS:—Eureka is to eastern Nevada as Virginia City is to the western, the principal mining locality, and the main center of all mining enterprise through this section of the State. Its population, including the miners of Ruby Hill, must be 6,000, though its attending school children are only about 275; but Ruby Hill has its school apparatus from Eureka. The fire of last April swept away two-thirds of the east half of the place, but the whole is rapidly being rebuilt more substantially and beautifully than before, except the northern and lower part, which is on some account delayed in its improvements. The Episcopal and Methodist churches, burnt in the fire, are both restored; the first by a neat small stone chapel, the second by a good stone basement, well finished and roofed for present use, the main story to be yet put up, as more funds shall be received for the purpose. The Presbyterian and Catholic churches were to the west of the main street, and hence were saved; as also was the school-house.

The International Hotel is likely to become greatly improved, in place of the structure burned, though the \$30,000 laid out for this purpose rather test the energy and resources of Mr. Hall, the enterprising proprietor. The Turner House, also, we would particularize, for the comfort of guests, and the neat, appropriate management of everything in the house.

A fine brick Court-house is being built, though there has been much public excitement because of alleged dishonest contracting.

The main machine shop and foundry of the place was burnt, yet slowly its restoration is going on, while one or two smaller shops endeavor in part to supply necessary work. Neither of the two active large mills for reducing ore was injured, though the Eureka, in the lower part of the town was in real danger. The Richmond, in the upper part, was wholly out of the range of the fire.

These two mills are now doing all the reducing for the whole district, though others are expected to start in the course of months.

From three to five immense furnaces in each mill are kept constantly charged, day and night, from year in to year out, smelting all the ore as it comes from the mines; consuming, in both mills, about 720 cords of wood a day, in the form both of coke and wood. A class of coke-burners, mostly Italians, have struck for a higher price, and resorted to arms to compel all to come to their terms, but the State authorities have taken the matter in hand, and doubtless the resistance will be crushed.

The process of smelting a stranger can never cease to admire. The two red-hot streams of melted ore are constantly running, one in front of each fiery furnace, and one at the side; the one in front a little the higher to drain off the upper, lighter, worthless matter, called slag, being earthy matter and iron; the other, lower, connected by a pipe deeper down in the melted mass, where the purer metals of heavier weight—lead, silver, gold, etc.—will not allow the surface to rise as high as the other. The fiery slag is wheeled off to be emptied from great kettles a burning stream down the front of the ever-increasing hill of waste. The metal is dipped into molds as bars, and wheeled away to a differently arranged furnace, melted over and skimmed, removing 5% of remaining impurity. From this furnace the mass is again drawn off into immense vats, and cooled in masses of over four tons. From here they are raised by power derricks, and put into another immense iron retort or furnace of 20 tons capacity, and melted, while heated steam, forced into the bottom, causes a violent hoiling of the liquid mass. At length a partial cooling crystallizes the lead in part, so as to appear like wet meal. Now, opening a vent at the bottom, the uncrystallized liquid portion, by its weight, rushes out, carrying with it three-fourths of the silver and gold in the mass, while the crystallized lead remains behind. The lead drawn off, is again put through the same steam boiling process, three or four times, each time the running mass carrying away three-fourths of the precious metals with it. At the last, the whole is put into a reverberating furnace, the heat of which burns away all the remaining lead as an oxide, and leaving the pure silver with all the gold the ore contained.

This last is called the cupelling process, and ends refining.

This is the method of the Richmond mill, but the Eureka has sent most of its lead bullion for the final refining to Newark, New Jersey. The Richmond retains its refined lead bars, stacked in immense cord-wood-like rows, thousands of tons, the purest lead in the world, but the markets are overstocked at present.

Ruby Hill, where all the mining is done, is a mile and a half southwest of Eureka, higher in altitude, so that narrow-gauge railroads easily bring down the ore to the mills. The mines are in hills mightily broken and rugged, while the many small houses are perched every way on narrow ridges, crazy edges, steep declivities, deep canyons, and a few easy roadsides, widening out gradually down into moderate valleys.

Here some 2,000 people, many families, live and toil in connection with the mines. Not a tree or a green shrub or tuft of grass do we re-

member to have seen, except to the southeast behind an elevation, where two or three apparently scorched small remnants of rough native pines, some miner in humanity had spared. Work and toil here, every day, is the one order of life, though they do have a moderate Methodist and also Roman Catholic Church, which a few will attend. But such mining life has a powerful tendency to un-Americanize, uncivilize, unmoralize, every being of the human race in this crowd. Those who will resist the tendency and rise victors over the evil influences are heroes indeed. It is certain that everywhere Americans must have a Sabbath of rest from usual business employments. The poor working men need it a thousand fold more than they need an eight-hour law.

These mines of Eureka or Ruby Hill seem sure and permanent for ages to come. The Con. Eureka, which is the lowest, is only a little over 900 feet deep, yet the ledges are large, productive and cool, with no apparent increase of temperature. The Richmond is much the same, while the Albion, the Phenix, the Jackson, and other mines are being vigorously worked with very favorable results. Also the Ruby and Dunderberg claims are just relieved from all judicial difficulties, and this vigorous English company is expected to press their work right forward with good success. Moreover, the range rises to the south regularly into a broken elevation called Prospect mountain, where of late much prospecting is being done, with good results, so far justifying much greater expectations for the future. There seems no good reason why this mountain may not surpass all other places in the vicinity in the large yield of rich ores.

S. V. B.

Kern County Mines.

EDITORS PRESS:—I have been up in this part of the country for about four weeks, and I suppose you would like to know something of what is being done in the mining department. I don't think there are over twenty quartz miners actually at work in this district, although there are a large number of very promising quartz veins in sight, on many of which work has been done in years past, and nearly all have, as far as I can learn, paid a profit. At present work is being done on the Grizzly claims, formerly the property of Mr. White, the Recorder of this district, and lately purchased by Messrs.

McNulty, Fletcher and San Francisco parties. The Grizzly claims are known as the Dreadnaught, Big Grizzly and New Constitution.

The main shaft of the Dreadnaught is down about sixty-five feet, in rich sulphuret rock which works \$150 per ton. The owners have, within the last ten days, built a whim for hoisting purposes, and are fitting up the mine in good shape with new track, cars, tools, etc. There is considerable water encountered, which may necessitate pumping machinery. The vein is fully five feet in width, and so far promises big things. Messrs. Cunningham & Co., owners of the Recompense, are still hard at work taking out ore, among which are found a great many rich specimens. They propose contracting with the mill for the crushing of from two to three hundred tons of rock within the next few weeks. The same parties have other valuable claims which I propose to examine. Mr. C. T. White has made a rich strike in a mine he owns and is working, near White river on Bald mountain. The ledge is about eighteen inches wide, and is very rich. A small force of men are working in the Eclipse and Lee mines, taking out ore and removing waste rock, etc., preparatory to further prospecting the mines. Messrs. Garrison & Biggs are mining on the south side of Bald mountain, sinking a shaft on their ledge. They have a strong, well-defined vein fully eight feet wide between casings, but not all pay rock. The old working has paid well. The Eclipse mill is running as steady as possible, considering that there is a short supply of water, which time will cure, and enable them to run night and day, as there is plenty of rock on hand.

As my letter is becoming too long, I will close by stating that portions of this district are fairly covered with quartz veins and placer mines which would afford employment for fully one thousand miners at much better wages than can be had in cities. This will be a good mining district. Heretofore it has been hitherto by adventurers, speculators and sharpers. Actual miners are now coming in, promising rich developments in the near future.

B.
White River, Kern Co., Aug. 15th.

COAL IN THE BLACK HILLS.—Explorations recently made by competent experts have demonstrated the existence of most valuable deposits of coal in the quarter of the junction of the Redwater with the Spearfish creek, in the Black Hills. Veins have already been opened up from five to six feet in thickness, and the coal, of the lower part of the strata, is so free from sulphur that it has been used for smelting purposes in the home foundries at Deadwood. There is no doubt in the minds of the experts that underlying the strata already discovered, and at no great depth, other coal formations will be found, greater in thickness and of better quality. The requisite means have been secured to make further explorations and to develop this beneficent source of mineral fuel so opportunely found in that quarter.

MECHANICAL PROGRESS.

Paving Streets by Steam.

A steam rammer has lately been invented and patented designed for paving streets, and intended for use in large cities, where the great extent of street surface is composed of blocks and cobble stones, which require to be more firmly imbedded in the earth than can be done by hand.

This machine is thus described: It is operated on the same principle as the trip-hammer, and can be so regulated as to make a stroke of one pound or 1,500 pounds. This enables the operator to produce a level surface on every portion of the street it passes over, while the most expert man-power cannot strike over 200 pounds. Durability and solidity are the important features of paved streets, and while hand-power can only force the stone into the earth three inches, the steam-hammer sends them six inches with ease, thus making the stones compact and solid.

It is claimed that the streets paved with this new invention will last until the stone is worn out. So solid are the streets rendered that the heaviest laden wagon or dray cannot affect the surface.

The present machine weighs six and a half tons, and even that makes no rent or impression on the street which it has rammed. In repaving streets with cobble-stones under the old system, it is necessary to relay them, while with the steam-hammer they can be driven to a level with perfect ease. It requires the services only of an engineer and a man to guide the rammer to work the machine, and it consumes but one-fourth of a ton of coal daily.

HOROGRAPH.—Instead of the electric pen, an instrument is in use in England for supplying the means of producing rapidly and cheaply any desired number of circulars, notes, examination papers or other writings. As its name implies, it may be said to be writing by clock-work, the mechanism and the moving power being all contained in the head of the instrument. The pen itself is a needle receiving a rapid up-and-down motion in a tube held in the finger like an ordinary pencil case. It is instantaneously stopped and started by the action of the thumb. The result of its operation is to perforate the paper with fine holes at the rate of nearly 10,000 per minute, at short intervals. The sheet thus prepared constitutes a stencil, over which the passage of an ink roller will give impression after impression of clear fine writing or printing, to a practically unlimited extent, and at a speed of 300 to 400 copies per hour. From one of these stencils 10,000 impressions and upwards may be printed. The machine is free from all complexity, so simple, indeed, that no personal instruction is needed, the printed directions which accompany it being all that are required for its efficient use. It can be carried in its case in the pocket, while the whole of the printing arrangements which accompany it occupy small room and are perfectly portable. The instrument is similar to the electric pen, without the wires and battery complications.

HEATING SOLDERING IRONS.—A simple apparatus has been devised by Dr. Paquelin, of Paris, for heating soldering irons with a gas blow-pipe flame. A metallic box of the size of a thick book, the inner arrangement of which is not stated, is placed by the workman in a side pocket of his coat. He connects it with two caoutchouc tubes, one of which goes to the soldering tool, the other to a small caoutchouc balloon lying on the ground. By treading on the balloon, air is forced through the box, and therein becomes charged with petroleum vapor. The soldering tool itself is hollow, and into it projects, at the fore end of the handle, a platinum point through which the air, charged with hydrocarbon, is blown into the interior of iron in fine current. In commencing work the platinum point is first brought to a glow in a neighboring spirit lamp; it inflames the gas mixture blown through; thus the iron is quickly heated, and kept hot so long as the blast is maintained. If a short interruption occurs, it is not found necessary to heat the platinum anew at the other flame.—*Ironmonger.*

NEW ELEVATOR.—At the test made upon the large passenger elevator at the Grand Pacific hotel, Chicago, lately, by Colonel A. C. Hillthorpe, for the purpose of demonstrating the absolute safety of his patent air-cushion. The elevator was raised to the fifth floor, 85 feet from the ground, to make a trial trip. In a pair were a dozen eggs, and in another were some delicate wine glasses filled with water; the rope was loosened, and the elevator fell to the ground, stopping without injury to the occupants—men, eggs, and glasses. The device by which this is effected is a box or vat with air cells placed at the bottom of the shaft, and below the first entrance way. The depth of the cushion is regulated by the height of the shaft. The bottom of the coach of the elevator is converted into a plunger with India rubber valves similar to any plunger for the purpose of pumping air or water. The falling coach carries the air with it, and breaks the concussion, and compels it to descend gently to the bottom, as may be seen from the fact that the water in the glasses was not spilled nor the eggs broken.

AUTOMATIC CLOCK.—Felix Meier, a Bavarian mechanic at Detroit, has built a clock which is said to surpass the famous Strasburg timepiece. It stands in an elaborately carved walnut case, 18 feet high and 7 or 8 broad, and has a dial which represents the entire planetary system, from the signs of the zodiac to the correct positions of the earth toward the sun in the different seasons, and the revolutions of all the planets about the sun at their respective distances and times. Separate dials also give the correct time at New York, London, St. Petersburg, San Francisco, and all the leading cities of the world. The big dial is supported by statuettes of William Cullen Bryant and Prof. Morse, and the case is surmounted by a bronze figure of Columbus. In carved niches at each side of the dial stands a baby, a youth, a middle-aged man, an old man and the skeleton figure of Death. The baby strikes the quarter hour on a tinkling bell; the boy, the half hour on a clear-toned bell; the strong man, the three-quarter hour on a full-toned bell, with a hammer, while the gray beard strikes a weaker bell, and then Death tolls the full hour. When the knell of the hour is gone a lively national air strikes up, and all the Presidents down to Hayes emerge from a door guarded by a colored servant, and file before Washington, who sits under a canopy surmounted by 37 stars at the top of the case. As the Presidents draw up in front of Washington, he rises and waves a copy of the Declaration of Independence. The Presidents salute him and pass across a platform and out of a door opened for them by another colored servant. Meier has spent 10 years and \$30,000 on this clock.

A NOVEL AND SWIFT VESSEL.—A steam catamaran is being built at Poughkeepsie, N. Y. It differs from anything in this line ever before designed. In some respects it is similar to an ordinary catamaran, the hull being in effect an ordinary hull split in two, the bulves being placed about fifteen feet apart, and the boarded perpendicular sides being exactly parallel to each other. These two half-hulls are joined together by heavy beams. The width of the deck is thirty feet and the length seventy. The hulls of Mr. Merritt's catamaran will be fifty-one feet on the keel, with only seven feet beam and five feet depth, so that while the deck is almost half as wide as it is long, the hulls are very long and narrow, and will displace little water and offer no more resistance than a single narrow hull. In each hull will be placed a twenty-five horse power engine operating two wheels, so that the vessel will have four wheels, two between and two outside of the hulls. The wheels themselves are of peculiar construction, being eight feet in diameter and of the kind known as the "feathering." The paddles are not fixed, but are moveable, and by a simple latching and unlatching process are held at right angles to the water while plunging into it, and while coming out are edgewise. Thus all the power is directly applied to forward propulsion, and none whatever is wasted in lifting or depressing the vessel. It is thought that this novel craft will be able to make thirty miles an hour.

AUTOMATIC SAND-BRAKE FOR RAILWAYS.—The *Engineer* in a recent issue describes the new brake of W. Wiseman, of the Indian government railway department. On the axle of every wheel of the train is placed a cylinder, in which a circular plate keyed to the axle and bearing a number of small blades, revolves whenever the train is in motion. The blade compartment surrounds a cylindrical compartment, which, being filled with sand, is called a sand-box. The upper and the lower portion of this box are in communication with the blade-box by a number of parts, of which the lower can be opened and closed by means both of an electrical mechanism and automatically, while the upper ones, which are smaller, are always open. A plate, keyed to the axle, opens the lower sand ports with every revolution, but the sand thus escaping is so small in quantity that it is immediately swept back by the blades into the sand-box through the upper ports. As soon, however, as the electrical circuit, which also controls this sand valve by means of an electro-magnet, is broken, the sand flows from the box very quickly, and, packing the blade-box, stops the train. The same will occur as soon as the train moves too rapidly or when one or more cars are left behind. It is therefore automatic, and its effect increases with the velocity of the train. Experiments made with a 7-horse power engine were quite successful and promising.

SOME OLD PATENTS.—The New Haven *Palladium* says: A gentleman residing in this city has in his possession *fac similes* of two certificates of patents, both being of interest because of their antiquity. One bears the date of 1715, and the patent to which it certifies was the first ever granted to a resident of the United States. The grantee was Thomas Masters, of Pennsylvania, and the invention referred to is spoken of as "a new invention found out by Sybilah his wife for cleaning and curing the Indian corn growing in the several colonies in America." The certificate includes a rough sketch of the machine patented, and illustrates a very simple manner of accomplishing the work for which it was intended. The other certificate shows a sketch of the first revolving gun ever made, which is very similar in design to the Gatling gun. The invention was patented in 1718, and its purpose was indicated by the inventor as follows:

Defending King George, your country and laws, Defending yourselves and Protestant cause.

SCIENTIFIC PROGRESS.

Sulphides as Fuel.

Mr. John Hollway has made a new application for rapid oxidation by which sulphides are utilized as fuel. The *London Journal of Arts* contains a long statement from Mr. Hollway, giving an account of his process. The matter is of interest from a utilitarian point of view, but principally from the better effects realized from the combustion of pyritous minerals hitherto regarded as nearly useless in the economy of man.

This process has for its object the utilization of the heat generated by the rapid oxidation of certain mineral substances which have not hitherto been used as sources of heat for smelting operations. The heat thus obtained is employed in the reduction of the furnace charge, which may be composed partly of sulphides and partly of siliceous ores. A current of air is forced through molten sulphides, by which means they are very rapidly oxidized. Great heat is thus developed, rendering the process of smelting a self-supporting operation; therefore no extraneous fuel is required, excepting that employed in raising steam for the blowing engines; where, however, water power is available, steam can be dispensed with, in which case all the carbonaceous fuel necessary for the operation is a little coke to start the furnaces, which stands in the same relative position to the ores as wood does to coal in the lighting of an ordinary fire.

It is well known that pyritous minerals are readily combustible, but the best means of utilizing the heat-producing property of metallic sulphides, is not so apparent as would at first sight appear. Of these sulphides, only iron pyrites is sufficiently combustible at a low temperature to burn in the open air, the mass being raised to the temperature at which the oxidation takes place solely by the union of sulphur and iron with atmospheric oxygen. In Spain there are numerous deposits of poor cupreous pyrites, and the Rio Tinto and Tharsis companies annually treat, at their mines, about 1,000,000 tons for the extraction of copper only, which does not average 2%. The process employed consists essentially in roasting the pyrites in heaps in the open air, dissolving out the copper from the roasted material and precipitating it from the solution by means of iron. These operations extend over several months, any gold or silver contained in the ore is lost, and the iron and sulphur are also wasted. The sulphur passes into the air as an obnoxious and annoying gas, desolating the country for miles around the works.

From the earliest ages, carbon has been considered a necessity in all metallurgical operations. The first reduction of metals by means of carbon forms a connecting link between the age of stone and the commencement of civilized art. It is well known that carbon burns at widely varying temperatures, as, for example, in our bodies, in a common coal fire, or in a furnace. A great deal of thought has been devoted to the subject of economizing carbonaceous fuel, and great advances have been made in this direction; yet the expenditure of coal or coke necessary, say to melt a given quantity of metal, still far exceeds the limit, because only part of the oxygen of the air passing into a furnace acts on the material to be burned, or is not brought in contact with the combustible matter with sufficient rapidity to obtain the necessary temperature for the operation.

In this new process the ores supply their own fuel. The process may be conducted in a Bessemer converter but fixed furnaces, with attached condensers, are more suitable. On melting a small charge of pyrites to start the operation, and feeding the furnaces with cold mineral, maintaining a powerful blast, a tremendous heat is produced by the combustion of part of sulphur and iron, and a variety of products are secured. Beginning with those that fly up the chimney, and are condensed, there are sulphurous acid, sulphur, arsenic, zinc, antimony and lead. Flowing from the furnace is a molten mass of what is called "regulus," containing copper, cobalt, nickel, silver and gold. This settles in the lower part of the receivers, and is covered with a slag composed mainly of silicate of iron. Among the adaptations to which this process is particularly directed is the treatment of auriferous and argentiferous pyrites. It is well known that in practice it is not possible to obtain the whole of the gold from pyrites by amalgamation with quicksilver, because the presence of sulphur and arsenic sickens and fumes the mercury, whereas by fusion the whole of the silver and gold present is obtained.

REPRODUCING DRAWINGS.—Many of the difficulties attending the method of blue tracings in Pellet's process the tracing appears in blue lines on white, instead of white on blue. Prepared paper is placed under the tracing, and is exposed to the light. After a sufficient time of exposure the prepared paper is dipped into a bath of yellow prussiate of potassium, which develops the lines of the drawings in blue. It is then washed and the excess of salts of iron is carried off by dipping the drawing into a weak solution of hydrochloric or sulphuric acid.

Ancient Human Skull.

From the diary of Thomas Besb of Loudon, who died in Colorado about one year ago, we give an abstract of the discovery by him of a human skull in a deposit, the age of which he was prevented from discussing by his sudden death. "In passing westward from the Missouri to the Rocky mountains through Nebraska, northern Kansas, Wyoming and Colorado to the upper member of the drift series, the equivalent of the brown clay of Illinois is found to be continuous up to the base of the mountains. Drift gravel is generally found below it or is contained in patches in it. Nearing the mountains the clay is of a darker color and a more sandy texture, and has often pebbles and stones scattered through it. Large boulders are also met with near the mountains, and beds of sub-angular boulders and pebbles, nearly always of crystalline rocks, skirt the flanks of the mountains, run up the sides of the valleys opening into them, and cap isolated hills in front of them to heights of about 8,000 feet above the sea.

"In the neighborhood of Denver the sandy clay covers the whole country, excepting on the steeper slopes, where it is sometimes absent denudation. It is often as much as 30 feet in thickness, and contains here and there boulders of crystalline rocks scattered through it. In some of the sections these are sufficiently numerous to make it a boulder-clay. Much of it is unstratified and with vertical joints.

"Whilst examining the sides of a cutting through this deposit on the Colorado Central railway, near the top of the low watershed between the South Platte and its tributary, Clear creek, I noticed a whitish substance on the face of the cutting. On clipping round it with a knife it proved to be the top of a human skull. It was in perfectly undisturbed loess-like clay, at a depth of three feet nine inches from the surface. At the same horizon at intervals were small angular pieces of miocene wood. No other bones were found, and none of the teeth. Seventy yards distant I found what appears to be a portion of a human rib.

"Isolated bones of other animals than man are not uncommon in the neighborhood of Denver and near the foot-hills in the brown clay and associated drift gravels. Besides those found by myself, Prof. Lakes, of Golden, and Mr. H. C. Tower, of Denver, have collected many specimens. Among these, bones of the common buffalo seem to be most frequently met with."

CONTACT OF MICROMETER SCREW.—Mr. A. S. Kimball, in an essay on magnetic strains in iron, describes a method used by him to detect the contact of micrometer screws, which is of value as it is applicable in very many physical and mechanical experiments. In the case in question the micrometer screw had 60 threads to an inch, and its head was graduated to 300 parts, so that the unit of measurement was the 1-18,000th of an inch. The iron bar, micrometer screw and a telephone were put in the circuit of a weak Lanchette cell. When the screw was turned up to loose contact with the bar, the familiar hoiling sound of a too sensitive microphone was heard, which ceased the instant firm contact was made, the change to silence being abrupt and sharply defined. The results, Mr. Kimball says, may be trusted to one-half divisions.

GIVING FLAX THE APPEARANCE OF SILK.—A Parisian has, it is said, succeeded in preparing from silk waste a liquid which will give flax yarn, chemically prepared, a silken coating. The new material has lost its resemblance to flax, and is in fineness, elasticity and gloss a perfect substitute for the more expensive article. The inventor prepared samples on the spot, and succeeded so well that 14 manufacturers, whose names are given, formed a limited company for the purchase of the invention at a cost of 3,000,000 francs. Two days afterwards the value of shares in the new company had risen 30%. Should the process prove a success, the entire silk industry and other textile branches will be revolutionized.

A NEW MAGNETOMETER.—This new instrument is the invention of G. M. Hopkins, and consists of a concaved, horizontal, metallic plate and a chambered vulcanite cap, which hold firmly between them a steel diaphragm. Through the stuffing box of the vulcanite cap passes a glass tube of small caliber. The chamber of the vulcanite cap, which is closed by the diaphragm, is filled with mercury, so that any movement of the diaphragm, upward or downward, causes the mercury in the glass tube to rise and fall, thus indicating the force of the attractive or repulsive force exerted on the diaphragm. An instrument of similar construction serves as an electrometer.

SINGLE STORY MILLS.—It is thought that before long the cotton mills of New England will be built with one story, instead of with five or six, as at present. The advantages claimed are increased safety and convenience and a higher speed for machinery. The report of a New England gingham factory on last winter's use of a one-story building was that it covered about an acre, was built of brick with corner towers at a cost of \$23,000 and saved in gas alone a sum equal to the interest on the cost of the building. The looms were driven at 12% higher speed than on the second floor of the old mill, the repairs were fewer, and less imperfect work was turned out.

The Mining Share Market.

Although the volume of business has not been great, owing perhaps to the political excitement attendant upon the near approach of election day, prices, however, have been well sustained. The decrease of the flood in the Comstock obtained a response from the shares of those mines, and somewhat higher prices are prevailing. All things considered, there appears to be some prospects of a revival of business after election.

Emigration of Miners from England.

We notice complaints in the English papers concerning the emigration of skilled laborers, resulting from the protracted depression in trade. They state that the mining population, especially, are turning their eyes towards "fresh fields and pastures new." Complaint is not made of the great numbers emigrating, but in the misfortune that in these cases the best and most reliable workmen have off first, so that if the exodus extends greatly, their loss will be felt when the good times expected arrive. Some are going to New Zealand, with free passage, and others are coming here.

On this coast the mining population is already large enough for the developments which are progressing. If we become overcrowded with miners, wages will naturally be lowered, and trouble among the men will ensue. We have not work enough at present here for our own skilled miners as it is, and any fresh influx is to be regretted.

Still if these men come with money enough to go to work on their own hook and develop new or partly opened mines it would all be very well; but they do not. They come expecting employment at daily wages, and crowd out our own men. These colliers are good miners when working under specific instructions, but they are not at all familiar with gold or silver mining, as Pacific coast miners are, so they don't try and do much in prospecting or opening mines.

Altogether we hope that any immigration of this sort will just at present cease. Our miners have hard enough times as it is to get steady work, and any further invading will bring harder times among them.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Bodie Con., Aug. 26th, \$20,700; Northern Belle, Aug. 23d, \$4,679.83; Christy Aug. 25th, \$7,004; Leopard, Aug. 26th, \$4,500; Grand Prize, Aug. 25th, \$7,000; Independence, Aug. 25th, \$6,200; Belle Isle, Aug. 25th; \$23,000; Hillside, Aug. 24th, \$4,400; Northern Belle, Aug. 20th, \$2,974.78; Con. Virginia, Aug. 20th, \$48,886.32; Martin White, Aug. 20th, \$5,225.60; Alexander, Aug. 22d, \$8,350.31; Northern Belle, Aug. 18th, \$2,807.91; Hillside, Aug. 21st, \$4,350.

BIG DEBTS.—The debt of the United States, less cash in the Treasury, amounts to \$2,027,100,265. Germany appears to have increased her small debt of late. The following will show the indebtedness of three nations at the latest returns, given in pounds sterling for convenience of comparison: Great Britain, £777,781,596; France, £967,584,280; Germany, general debt, £2,544,083; Germany, railroad debt, £13,862,656. The consolidated annuities of England, known as "Consols," pay 3% per annum.

INCREASED TRADE.—American trade with Austria has increased enormously since the Vienna exhibition, when the people got their eyes opened to the superiority of American inventions, farm implements, tools, etc. Hundreds of thousands of sewing machines have been sold in that country, and farmers who have the means are rapidly supplying themselves with labor-saving implements of American manufacture.

The Russian and English commissioners are having trouble about the Russo-Turkish frontier.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

VOLADOR DISTRICT ITEMS.—Ledger, Aug. 23: A remarkably rich body of quartz is being operated upon by Brown & Co. on Pioneer creek. A clean-up from this rock, lately made at Mac's mill, yielded an average of \$70 per ton. A mass crushed by hand mortar 500 pounds of rock from this recently discovered ledge, a few miles from Volador, and obtained the handsome result of \$125. He has a shaft sunk 29 ft., and the ledge shows from 8 to 10 inches in width. At the Downs mine sinking operations are progressing. The shaft is already down about 30 ft below the levels, and the ore body shows richer than ever at the bottom. A thorough clean-up is being made at the Grass Valley mine. At the Golden Gate the work of pumping out water from the shaft has been going on for a month past. The water is now all out, and a ledge of good-looking quartz appears at the bottom of the shaft. Sinking is the order of the day on the Confidence mine.

MONO.

MARYLAND CON.—News, Aug. 24: The new shaft has been straightened and sunk to a depth of 55 ft., and today shifts were put on at the lower level of the old incline, to crosscut and raise from a point vertical with the new shaft. The new machinery arrived at Carson yesterday, and the Chief Engineer, Mr. Rollins, who has the station in charge, will forward it without delay to the mine. The foundation for the new building is all laid, and the galleys frame ready for raising.

VORTEX.—The winze from the north drift on the 250 level has reached a depth of 52 ft., and is still being sunk with all possible speed. It is the intention to connect with the west crosscut now being run from the Osceola, which will be reached at a depth of 40 ft. The ledge in the incline is still looking well and is two ft wide, of good ore. The company will commence work within a few days in the lower tunnel of the Syndicate, for the purpose of cutting the ledge at a greater depth.

BLACKHAWK.—Main shaft is now down 328 ft., and still sinking. Winze on 320 level, on Warren vein, is down 140 ft., in a varied formation which looks well. The east drift is now in 100 ft from the shaft, and looks remarkably well.

SOUTH NOONDAY.—Still drifting north on the ledge, which is looking remarkably favorable for the near presence of an ore body. Will continue to drift until the mine is thoroughly opened and ready for more extensive work and exploration.

SOUTH BLYNDER.—Now engaged in crosscutting east on the 150 level, making good progress. Will cut the ledge at a distance of 60 ft from the shaft. Everything looking exceedingly encouraging about the mine.

UNIVERSITY.—Shaft down 32 ft., in a formation of porphyry and clay, mixed with quartz, which all assays well. The boiler has arrived and the other machinery will soon follow, when all will be put in position.

SOUTH BELVER.—Still drifting and sinking on the 350 level on the ledge. In the face of the drift the ledge is looking well and is three ft wide of good milling ore. Winze No. 2 has attained a depth of 62 ft., and the ledge looks well in the bottom, being two and one-half ft wide of good ore. Still driving the west crosscut on the 420 level, and have made about nine ft during the week past. Formation encountered very favorable, showing small strata of good-looking quartz.

SOUTH BODIE.—Chloride, Aug. 23: The company's ground is on Silver hill, Bodie district, south of the Mono mining company's ground, and north of the north Noonday, and covers an area of 600 ft by 1,500 ft. The shaft is situated at a point on the lode line 500 ft south of the northern boundary. Work was commenced on the 25th of August, 1878, by sinking and timbering the old Hancock shaft 40 ft deep, and crosscut 75 ft east from the bottom of the shaft. The formation encountered decomposed porphyry, clay and quartz, which had the appearance of a good, strong vein, the ore of which gave good results, both in gold and silver. The main double compartment shaft has been sunk to the depth of 520 ft., and a crosscut run east 507 ft. The face of the drift is at present in a hard bar of country rock, the footwall of regular porphyry. When this has been passed through it is expected to intersect the veins passing through Silver hill, from the Mono to the Noonday.

DUNDREBERO.—Bodie News, Aug. 22: This old mine is situated 15 miles west of Bodie on the east slope of Castle peak, the ledge has massive croppings, and is opened by a cross tunnel 600 ft in length, cutting the vein 200 ft deep. Drifts have been run 300 ft on the vein, which is from 2 to 5 ft wide, exposing fine ore everywhere. The character of the ore and of the country rock is different from that of Bodie, and likewise from the great mines of the western slope. Metallurgical difficulties, which may now be easily overcome, have retarded the development of this valuable property.

NEVADA.

ITEMS.—Foothill Tidings, Aug. 23: About 75 men are employed drifting in the various claims at Lowell Hill, and about \$5,000 paid for labor monthly. A fine ledge of gold-bearing quartz has been struck in the Surprise Con. mine, near Allison ranch. The new machinery of the Iron Clad quartz mine, near Rough and Ready, is about starting up steam. A rich strike in quartz is rumored to have been made in the neighborhood of Chapman's ranch, on the Nevada coast. A clean-up of tribute rock, amounting to \$1,100, was made from Alaska rock on Wednesday. The tributers realized \$5 per day to the man. There have been filed with the Secretary of State articles of incorporation of the Original Empire mill and mining company, to mine in Nevada county. Principal place of business, San Francisco. Capital stock, \$5,000,000, divided into 50,000 shares of \$100 each. Directors—Robt. Sherwood, J. B. Farns, Deles Lake, Cameron Alexander and W. B. Brown, all of San Francisco.

ROCKY BAR MINE.—Transcript, Aug. 21: The ledge in the slopes at the Chavanne shaft is of good size, and produces an excellent quality of rock. The same may be said of the ledge in the new shaft, from which the largest part of the rock from the mine is taken. The quartz yields quite evenly, always leaving a fair margin of profit to the company.

DEER CREEK.—A number of veteran miners have since last winter commenced prospecting for quartz along the banks of Deer creek east of Nevada City. Two or three of them are making considerable money, and others are developing ledges just found that promise to pay uncommonly well.

MEXICO.—The newly-developed mine in the old Gold Tunnel claim improves in size and richness. The new strike appears to be another vein in the series that comprise what is believed to be a true fissure.

WASHINGTON MINE.—Grass Valley Union, Aug. 26: The machinery and shaft are completed, and lateral drifts are about to be run. A large and well-defined ledge has been encountered in the north drift.

ORIENTAL MINE.—Transcript, Aug. 23: Twelve shaft men and an underground foreman were sent up to the Oriental mine yesterday morning. Thirty more will be put to work next week. The main shaft, which is now 470 ft deep, will be sunk still further, and the east and west drifts on the 450 level will be pushed ahead rapidly.

PLUMAS.

"NATIONAL MINE."—National, Aug. 23: The mill of this mine is to be enlarged to 60 stamps. Recent developments have shown plenty of quartz in sight to feed double that number.

SIERRA.

ITEMS.—Messenger, Aug. 23: The Black Jack quartz claim, at Jim Crow canyon, 8 miles east of Forest City, is being prospected with a view to put up a mill. The Black

Jack ledge is between 2 1/2 and 3 ft thick, and the rock taken from it while prospecting recently is said to be rich. The tunnel in the Savage mine is being put in at the rate of about 3 ft in 24 hours, through rock almost as hard as cast iron.

NEVADA.

WASHOE DISTRICT.

NORTH BONANZA AND FLOWERY.—Gold Hill News, Aug. 27: The drift north on the 300 level, and just inside the ledge, is moving regularly forward and disclosing some fine looking quartz veins. From a point in this drift 350 ft north of the shaft a crosscut has been started west, which is moving slowly forward and showing some good ore. Another crosscut was started last evening from a point in this drift 75 ft north of that mentioned above. The crosscut on this level in Flowery ground has been temporarily delayed by putting in the turn-tables for the two lateral drifts running north and south from it. On the 400 level the lateral drift, which has been swung around into the ledge for a crosscut, but has not yet reached the vein. The flow of water struck last week in the bottom of the shaft is still strong and prevents sinking. It is kept down, however, by the pumps and a little help from the giraffe.

GEN. VIRGINIA.—The north drift on the 1050 level is making four ft per day through favorable-looking vein matter carrying bunches of ore; total length, 112 ft. The crosscut east, 2150 level, is averaging three ft per day through vein material containing streaks of quartz; total length, 152 ft.

LADY BRYAN.—The north and south drifts on the 750 level continue in favorable vein matter, and preparations to raise the incline from this level to the 600 level are now completed. The west drift from the south drift on the 600 level is in a soft vein formation carrying low grade quartz and seams of fair grade. The north drift on this level continues in quartz of low grade. The east crosscut from this drift is in quartz and porphyry carrying some metal and looking well.

MR. HOOD & VANCOUVER.—The drift on the 1400 level is now in 400 ft, the face in good working ground. The ventilation in the drift has been greatly improved by placing in it a partition, allowing the fresh air to go in on one side and out on the other.

ORINA.—The station set at the 2400 level of the incline has been put in place and the incline continued six ft below it. When depth sufficient for a pump has been attained, the station will be opened and crosscuts run into the ledge. The materials are promising. The north drift, 2200 level, is averaging four ft per day, total length, 139 ft. The face is still in vein matter carrying streaks of clay and some water. Two ft per day are being added to the depth of the joint Mexican winze from the 2100 level; total depth, 70 ft. The porphyry encountered contains considerable water, which hinders the work. The west crosscut from the north drift has been discontinued in order to push the drift itself along to explore the Hardy vein in that direction. The joint Mexican crosscut, 2000 level, is averaging three ft per day, and is now in 72 ft, and in porphyry. The main north drift has been enlarged and timbered and made a thoroughfare for the mine. The ore breasts yield as usual and preserve their usual appearance.

JACK.—The lateral drifts along the west ore chamber and mining both north and south are in exceedingly promising ground containing spots of nice ore. The drift south on the 1650 level from the Alta is making good progress through favorable-looking ground.

SILVER TUNNEL.—The north lateral drift is being pushed ahead rapidly, and better progress is being made in that running south. A prospecting drift has been started in a vein of ledge matter cut through at a point 12,000 ft from the entrance, and some fine assays have been obtained. The drift is supposed to be the Occidental ledge.

GOLDEN STANDARD.—Encouraging prospects are still being met with in the Standard tunnel, the face showing quartz boulders of a very promising character; 90 ft yet remaining to be made to connect with the Homestead shaft.

CALABONIA.—The winze from the 1600 level is nearing the 1900 level, and carrying considerable water. The bottom is in bird's-eye porphyry, containing some water. The main shaft has passed the 800 level and is being continued on down. The flow of water into the shaft continues strong and the rock hard.

YELLOW JACKET.—Work in the mine is confined to sinking the incline winze from the 2500 level to the 2700. The winze is now down 245 ft on the slope below the former level, and making good progress. The work of sinking a shaft for the shaft below the 2700 level has been commenced.

GOULD & CURRY.—The joint east crosscut, 1700 level, is averaging four ft per day; total length, 1,160 ft. The joint shaft has, during the past week, passed the 700 level.

ALTA.—The rock encountered of late has been a harder formation of quartzite, carrying considerable water. The flow amounting to 140,000 gallons per day, which is, however, readily handled. A drift has been started from the bottom of the shaft on the 1550 level and is being pushed west toward the ledge. It will have something like 200 ft to run to get to the vein. The raise in the ore body from the 1550 toward the 1450 is continued.

CALIFORNIA.—After having been driven 550 ft west from the shaft, the joint crosscut on the 850 level has been discontinued and a drift commenced north from a point 63 ft from the face; total length of this drift, 15 ft. On the 2150 level the north drift leading to the Ophir is still being cut down. The work of dismantling the C. & C. shaft of pump rods down from the surface is going on, preparatory to replacing them with new 14 by 14 sticks to drive the double crosscut, 12-in. diameter, to the bottom. The work of changing the system will take about two years.

SAVAGE.—The water stood this morning between 125 and 130 ft on the slope below the 2100 level. The work of enlarging and retimbering the south winze is making good progress; total depth, 76 ft. Bulkheading the crosscut from the station, 2100 level, 200 and odd ft east, in hard blasting ground, and making a reservoir, so that the water can be pumped from the 2200 station up to the tank and thence to the 2000. This will be done with No. 8 or 9 donkeys, and thus the force brought to bear on the water will be doubled.

UNION CON.—The joint Mexican crosscut west, 2000 level, is in a soft vein formation, carrying clay and quartz in streaks; total length, 60 ft. The joint Mexican winze is down 30 ft in porphyry, carrying considerable water. **MEXICO.**—The joint Ophir winze from the 2100 level is down 70 ft and in porphyry carrying considerable water, which interferes with the sinking. The joint Ophir crosscut, 2000 level, is in vein porphyry, its face 72 ft from the lateral drift. The joint Union crosscut is averaging four ft per day; total length, 60 ft, the face in a soft vein formation carrying clay and quartz in streaks. The joint Union winze is down 40 ft, the bottom in porphyry carrying considerable water.

ARGENTA DISTRICT.

ITEMS.—Tribune, Aug. 23: A valuable discovery of ore in the Oliver Twist mine has been made. The Sedan is down 60 ft, with a good ledge in the bottom of the shaft.

BELMONT DISTRICT.

ITEMS.—Courier, Aug. 23: Raise from 200 south level was advanced 16 ft through a small streak of high-grade ore. The slope south of raise is looking fine and yielding two tons of \$100-ore per day. Raise No. 4 was advanced 36 ft during the past week through a vein of quartz two ft thick showing little bunches of nice ore. A drift south from No. 3 raise under the ore body was started and advanced 15 ft. Work has been resumed in the south drift of the Gila. The vein still holds its width (about four and one-half ft), all of which is good ore, and a part of it very rich. The slopes are all looking well and turning out a large quantity of ore, which is being hauled to the mill at the rate of about nine and one-half tons per day.

BRISTOL DISTRICT.

HILLSIDE MINE.—Tribune, Aug. 23: The discovery of

a very large body of high-grade lead and silver ore has been made in the west drift on the 400 level.

CENTRAL DISTRICT.

SURPRISE MINE.—Silver State, Aug. 22: The mine is opened by shaft to a depth of 100 ft, and there is said to be considerable good ore in sight.

CHIMNEY CREEK DISTRICT.

ITEMS.—Winnemuccia Silver State, Aug. 25: Reports reach town of several very rich strikes having been made recently in Chimney Creek district. The Henry Clay, a new discovery in that district, owned by Messrs. S. B. Palmer, Fish, Luther, and others, is said to be a rich claim. This district is situated between two high mountains, with wood, water and grass in abundance, easy of access, making it one of the most attractive and convenient in the county.

COMO DISTRICT.

ITEMS.—Reno Gazette, Aug. 16: The Como mines are reported as looking well. There are about 60 miners there now. The Eureka had 50 tons of rock crushed at Dayton, which went \$17.75 per ton. The ore carries both gold and silver, and is free milling.

ESMERALDA DISTRICT.

DEL MONTE.—Emeralda Herald, Aug. 23: Work is still progressing at and around the mine. The immense galleys/frame was placed in position yesterday. The tunnel in the main tunnel was completed on Thursday and now only 25 ft remain to be run before connection is made with the main shaft. The work of getting the mine on wheels into place has been slow, but is finally accomplished.

EUREKA DISTRICT.

ITEMS.—Sentinel, Aug. 22: In the shaft of the Wales Con. there are some very good ore. The general appearance of all the mines in this district is improving.

FLOWERY DISTRICT.

BROPHY MINE.—Gold Hill News, Aug. 23: At the Brophy mine, Flowery district, the tunnel, at its face, is cutting ground from the seams in which issue strong currents of foul air and gases. These gases are not only foul-smelling, but also quite dangerous. Streaks of quartz and pay ore are also coming in, and from all these indications it is thought that the main ore body cannot be far away.

PARADISE DISTRICT.

ITEMS.—Reporter, Aug. 23: Preparations for the laying of a railroad track are being made in the lower tunnel of the Big Prize. The Big Prize mine is looking well, and yielding some good ore. At the Paradise company's mine a number of carpenters and graders are at work putting up a new ore house below their lower tunnel, through which all the ore will pass in the future. The ore now in the face of the drifts, shafts, etc., is as good, if not better than any yet extracted from this mine. Foreman Boyle now has 60 men at work in and around the mine, and expects to be able to break out 40 tons of ore per day, if required.

PIOCHE DISTRICT.

MAYFLOWER MINE.—Pioche Record, Aug. 23: A new and important development has been made in this mine. In sinking the winze below the 130 level, at a depth of 70 ft from this level, soft ore was encountered, assaying \$135 per ton. The extent of this body of ore is at present unknown. At this point the ore body is the full width of the winze—about four ft—and from all appearances much wider.

SIERRA DISTRICT.

ITEMS.—Silver State, Aug. 23: Several old mine claims in this district are about to be worked. They are the Lang Syne at Dun Glen, the old Anderson at Unionville, and the Eagle at Spring Valley. The Lang Syne is yielding pay ore. In the Lucky Dog a large ledge carrying rich ore has been developed at a trifling expense.

ARIZONA.

ITEMS.—Phoenix Herald, Aug. 20: Parties have struck a large deposit of ore, which will produce a large amount of free gold, and if it holds out their fondest hope will be realized. A specimen that weighed an ounce and a quarter yielded 75 cents in gold. The Chamberlain mine, two miles east of Globe City, is developing finely and bids fair to be one of the best mines of the district. The 600 level is still in ore which assays from \$40 into the thousands, and all is free-milling ore. The crosscut on same level shows ore nine ft wide. There is now on the dump 100 tons of milling ore. Work is steadily going on in the Richmond basin. Every claim being worked shows rich ore. Native silver is extracted from the west shaft of the La Plata. Bilderback's claim, the Great Western, is producing fine chloride ore; their ledge is two ft and gradually increasing in width. Joe Brewster is striking chloride and sublimed ore in the Last Chance, a claim he has lately opened. It runs up to the south line of the Mack Morris claim on the west end. The ores from the Davis mine, belonging to the Prescott mining company, have been found rich enough to ship to England for reduction, and the returns were so satisfactory to the owners that, after deducting the heavy expenses on the ore, for mining, transportation and milling, they had a large surplus of money on hand. The "E. F." and Eastern Slope mines produce gold and yield largely. The Golden Chariot mine, Groom creek, is being opened by shafts, the deepest of which is now down about 40 ft. The ore at this depth is very rich in free gold. The Manhattan mine, Hassayampa district, is yielding rich gold rock. A shaft is being sunk on the west extension of the Richmond with a good prospect of striking rich ore.

GLACE DISTRICT.—Silver Belt, Aug. 22: The Gould & Curry mine, a recent location south of Pinal mountains, shows a two-ft vein, assaying \$51 in gold and \$3 in silver. In the Pioneer mines drifting from the shaft each way at a depth of 47 ft. The breasts are full of ore and is being mined with a view of having it reduced at the Isabella mill.

COLORADO.

ITEMS.—Prospector, Aug. 15: The Diamond drill, at work on the Denver lead, at Silver Cliff, Custer county, yesterday struck four ft of native copper, the mineral seeming to be in nuggets. In the "Favorite" lode they have struck a large body of sand carbonates, as rich as they can be. In shaft No. 2 of the Lone Star mine, in the carbonate belt, a bed of carbonates of unknown depth and width, carrying from 50 to 800 ounces silver, was uncovered 60 ft from surface, and the mineral is so easily worked that the output with one shift of men ranges from 8 to 10 tons daily. In the Little Nell the owners have found a deposit of carbonates 22 ft down, that mill 27 1/2 ounces silver and run well in lead. The Bessie, Katy Didn't and Favorite have an apparently inexhaustible bed of carbonates above stated, and the thickness of the ore is down 55 ft in the Gov. Pitkin lode, one mile north of Blue mountains. A shaft has been sunk to the depth of 25 ft, following a three-ft vein of quartz which, at the depth of 10 ft, showed 10 ounces silver and 2 1/2 copper, with a few dollars in gold. The Britannic tunnel, in Clear Creek county, is driven into the southern slope of Revenue mountain a distance of 1,025 ft. Fourteen lodes are intersected thus far, the majority of which are profitable fissure veins of gray and yellow copper ores with galena containing silver. The Little Olly Clinton and Eagle Bird, locations of Eagle River mines, show a bed of mineral-bearing material from 12 to 15 ft in thickness. An incline has been run upon these lodes some 25 ft, and from the breasts shafts have been sunk, giving the thickness of the ore as above stated, and in yet no lime-bed rock has been reached. A rich strike of ruby silver has been made in one claim on this main contact from which assays were made in this city giving 1,743 ounces and 2,400 ounces to the ton.

ITEMS.—Fairplay Flume, Aug. 14: Big Sacramento is coming to the front as a carbonate producer. The Tennessee lode is said to show a fine body of mineral of that character.

[CONTINUED ON PAGE 140.]

Magnetic Strains in Iron.

A. S. Kimball, Professor of Physics in the Worcester Free Institute of Industrial Science, gives an interesting paper to the August number of the *American Journal of Science*, the object of which is to describe certain experiments made by inducing a magnetic state in bars of soft iron subjected to varying degrees of mechanical stress. As the result, we always have changes either in the form or dimensions of the bar, similar to those produced by the mechanical stress previously applied, and therefore the term "magnetic strain" does not seem inappropriate. Some of the phenomena hereafter to be described have been observed by earlier investigators. These experiments have not been repeated with the expectation of detecting errors in their work, nor of attaining a higher degree of accuracy, but rather, to afford that valuable check which the reproduction of well settled phenomena, with a new disposition of apparatus, affords, both upon the accuracy of the instrument and the skill of the operator.

Effect of Magnetization upon the Tenacity of Iron.—The pieces of iron tested were pulled asunder by a Fairbanks testing machine of 53,000 pounds capacity. The machine consists: 1. Of a large platform scale; 2. of a powerful screw-straining apparatus, driven by a belt from a shaft having eight changes of speed (the motive power is a Corliss engine which runs with great regularity); 3. an automatic weighing attachment to the beam, by which it is kept constantly poised as the stress is applied to the test piece.

The delicacy of this adjustment was such, that when the testing proceeded at a suitable rate, the deflection of the beam from the zero point did not indicate a stress on the test piece differing more than two pounds from that shown by the position of the poise on the beam. The scale was "sensitive" to the addition of one ounce when the platform was loaded with 4,000 pounds; and on the removal of the small weight, the beam promptly returned to its normal position. The course of experiment was as follows: Several pieces of the same kind of iron, made as nearly as possible uniform in size, were broken in the machine. The alternate ones, in the order in which they were cut from the bar, were magnetized to saturation by a helix, through which a constant current was passing during the experiment. The heating effects of the helix were slight, and probably without influence. The tabulated results were then compared, and from them the following conclusion was reached: A soft iron bar has its tenacity increased about nine-tenths of one per cent. by magnetizing it to saturation.

Another series of experiments upon telegraph wire gave 8.9 pounds difference between the means. Seventeen pieces of wire were broken. A series of 10 wires, one-quarter of an inch in diameter, gave an average of unmagnetized pieces, 4,532 pounds; of magnetized specimens, 4,572 pounds; difference, 40 pounds.

Some hundreds of pieces were broken with the same results. A magnetized piece always proving stronger than the unmagnetized pieces taken from the coil or bar on either side of it. A few apparent exceptions to this rule showed flaws in the tested pieces on close examination. The average increase of strength in these experiments is very near nine-tenths of one per cent. In every case the strength of the unmagnetized pieces was much more uniform than that of the magnetized. In the "Philosophical Transactions of the Royal Society," 1874, page 571, Sir William Thomson predicts this result as a deduction from Mr. Gore's experiments on electro-torsion.

Effect of Magnetization upon the Flexure of a Soft Iron Bar.—Joule's experiments upon the changes in dimensions of an iron bar when magnetized, formed the starting point for this part of the experimental examination in question. He has shown: 1. That if an iron rod be compressed longitudinally, it will be slightly elongated upon being made a magnet by a surrounding helix. 2. That the amount of compression does not affect the magnetic extension so long as the magnetizing force remains the same. 3. That the same phenomena, in kind and amount, occur in a bar which is neither compressed nor stretched. 4. If the bar be subjected to tension, the elongation, on making it a temporary magnet, is diminished, and as the tensile stress increases, the magnetic elongation diminishes through zero and becomes a shortening. 5. Prof. Mayer has shown that, in the case of an unstrained bar, the first passage of the current elongates the bar more than any subsequent passage of the same current, and that the second, third, and all subsequent elongations of the bar by a constant magnetizing force, are equal to each other; also that the shortening of the bar upon breaking the current is constant and equal to the second elongation. These facts, taken in connection with the common theory of flexure, fairly indicate one or two phenomena which will be found to attend the induction of a temporary magnetic state in a bar strained transversely. We see, from what has been said, that the neutral axis, and all the fibers on the concave side of the bar which have been shortened by compression, will be elongated by the action of the magnetizing force, while the fibers of the bar on the convex side, which have been subjected to tensile strain, will either be elongated by a less amount or will be shortened. As the result of this action we may be tolerably sure that the bar will be

straightened. It is much safer, however, in this case, to proceed with our investigation experimentally, since neither the theory of magnetic action in iron, nor that of transverse elasticity, can be said to have been fully developed.

The apparatus used in this part of the investigation was simple. A very rigid iron casting, with supports for a micrometer screw, and the ends of the iron rod to be examined upon its upper side, was placed upon the platform of a Fairbanks scale. The iron rod, carefully freed from magnetism and enclosed in its helix, was adjusted upon its supports so that the point of the micrometer screw was just below its middle. The helix was made in two parts for convenience in loading the bar. The middle of the bar supported one corner of a triangular platform, whose sides were four, eight and nine feet. The other corners of this platform were supported upon points. This disposition of apparatus proved very satisfactory. The load upon the bar was easily and accurately determined by the scales, while the stability of the triangular platform permitted the addition or removal of weight without seriously disturbing the adjustment of the bar. The micrometer screw had 60 threads to the inch, and its head was graduated to 300 parts. The unit of measurement is therefore 1-18000 of an inch. At first, contacts of the screw with the bar was determined by an electric bell, but the probable error of setting the screw being greater than one division of the screw head, a more exact method was sought. The following device was finally hit upon, which gave results which may be trusted to one-half divisions. The iron bar, micrometer screw, and a telephone were put in the circuit of a very weak Leclanche cell. When the screw was turned up to loose contact with the bar, the familiar boiling sound of a too sensitive microphone was heard, which ceased the instant firm contact was made. The change from the loud boiling sound to silence was abrupt and sharply defined. In the writer's experience this is by far the most reliable method of determining the contact of a screw.

Agricultural Machinery at the Mechanics' Fair.

The exhibit of agricultural machinery at this year's Mechanics' fair is in some respects better than it has been for several years. It is true that we miss some of those who have been prominent exhibitors at former fairs, and whose goods we would like to have seen this year, but there was increased effort on the part of others, and the space is all occupied. We are disposed to call this year's display better than usual, because the machines are not shown as "lay figures," but are rattling, rolling, thrumming and roaring away, performing mimic duties with all the precision and fullness with which they do actual work in the field, the grain barn or the warehouse. This, of course, gives life and interest to the agricultural department; it makes a noise in the fair world, and people stop to look at it.

This change in the character of the exhibit is due to the enterprise of Marcus C. Hawley & Co., for they have in their space one of H. W. Rice's strawburning engines which, taking its steam from the main boiler, turns all the machines shown by the firm. This engine of Mr. Rice's is a piece of agricultural mechanism to be proud of. It embodies all his latest improvements, and it is finished in a style which justifies us in saying that it is the handsomest agricultural engine we ever saw. The boiler is neatly lagged with colored woods, the iron work tastefully painted and adorned; the brass well polished, and the machine in every way a model of good workmanship. We have spoken mainly of the finish, because the efficiency of the engine for the uses contemplated has been frequently remarked. The engine was helmed directly to a large Gold Medal separator, which was running very smoothly. By means of counter shafts the engine was turning the geared parts of a large header, a harrow feed grinder, and a power cornsheller of Adams' self-feeding pattern. M. C. Hawley & Co.'s exhibit also included a champion fanning mill, Buckeye mowers, and a large assortment of plows. There was also within the enclosure handsome specimens of R. L. Knapp's side-hill plow, made at Half-Moon Bay, San Mateo county, and of which we had good accounts last fall from those who had used it. It is certainly worth the examination of hillside farmers. It is also well adapted for use as a reversible plow on flat land.

Another firm making a varied and excellent display of agricultural implements is Frank Bros., of this city. Their exhibit is well arranged, and includes many standard and new devices. The most striking feature of the display is a Walter A. Wood's self-binding reaper in full rig, which all those who do not have opportunity to see it in the field should certainly examine with care. This is one of the latest triumphs in harvesting machinery, and is already one of the most famous. Frank Bros. have also a full line of plows, including the Browne gang, and the Browne sulky, and single plows handsomely made and adapted to different requirements. They also show the McSherry grain drill, the La Belle wagon, a hand cider mill, feed cutter, etc. We noticed also the Deane cultivator, evidently a powerful implement and adjustable to a variety of cultures. The exhibit in general is a very creditable one.

David N. Hawley, another of our well-

known implement dealers, makes a display of several popular implements, including the Newton wagon, Meyers' excelsior gang plow, meadow king mower, Archimedeal-lawm mower, etc. He gives considerable space to an exhibit of scales adapted to all uses, beautifully finished, and so far as we could test them, very accurately adjusted.

A novel device, which will attract much attention, is the fruit picker of L. H. Titus, of San Gabriel, Los Angeles county. It consists of a ladder mounted upon a light truck, and beside it is a large circular hopper of canvas, into which the fruit falls, and rolls into a basket below. It seems well calculated to aid in quick work, and to preserve the fruit from injury.

Another California made implement is Dalton's gang plow, made at the Pacheco foundry, in Contra Costa county. It is well finished, and seems to be well designed for effective work. Many of our local shops are doing good work in plowmaking, and the Pacheco foundry is evidently one of them.

The windmill features of the fair are maintained by the Iron Turbine wind engine, introduced to this State this summer by D. E. Goldsmith, of 419 Sansome street. It has already commended itself to many of our wind-power users, both for its mechanical principles and material employed in its construction, and bids fair to become a popular machine.

There is a good show made of harrows of California manufacture. Gas-pipe harrows, folding and otherwise, are shown in good variety, but without the exhibitor's name attached. Another California harrow is named the "Farmer's Friend" or "Channel Iron Harrow," patented by N. Beauregard, and shown by the agents of J. Smith and R. Hoppe, of 318 Pine St., S. F. It is made in three independent sections, with 24 steel teeth to each section. Thus it adapts itself to inequalities in the surface. The leading points of the harrow are the style of the tooth and its manner of fastening to the bar. As the tooth is grooved or channeled on two sides, it is lighter than the solid tooth and yet strong, and by its shape it keeps itself sharp. Each tooth is held to the harrow by an iron strap tightened by threads and nuts. Thus it cannot work loose, but can be loosened and lowered easily when the point wears up. These features are novel, and seem worthy of examination.

Messrs. Hendry & Lennon show an object of peculiar interest in the shape of the first iron casting ever made in this State. It was made in 1850 to replace a broken part on one of the argonautic ships, and if it be viewed in connection with some of the massive casting now turned out from our foundries, one can get a good idea of the progress made in iron founding during the short industrial life of our State. Messrs. Hendry & Lennon also make a show of iron wheelbarrows which is interesting.

Adjoining the agricultural implement department, Mr. James, of Visalia, shows some of the mechanical appliances of his one-track railway, which is now attracting much attention among those who are considering the construction of cheap railways. He seems to secure a very effective and simple application of power to the work of propulsion, and we trust the value of his devices will soon be demonstrated by the construction of a working one-track line.

NORVEGIUM.—A new metal of the above name has been discovered in the nickel ores of the island Otero, near Krage, in Norway, by Tellef Dahll. The ore is calcined to remove sulphur and arsenic; it is then dissolved in acids and sulphureted hydrogen used as a precipitant. The precipitate, free from nickel, is washed and calcined. It is redissolved in *aqua regia* and precipitated by caustic potassa, avoiding an excess, in which the oxide of norvegium is soluble. The precipitation is not complete, a portion of the new metal remaining in solution. The precipitate, a hydrated oxide, is emerald green. It may be very readily reduced by fusing with charcoal in a crucible or by a current of hydrogen. The metal is white, to a certain degree malleable, as hard as copper and fusible at a dull red heat. Its specific gravity is 9.44. It is soluble with some difficulty in hydrochloric acid, and readily in nitric acid, the solution being blue, but changing to green when diluted with water. Assuming the oxide to be NiO , the equivalent of norvegium is 145.95. Its salts are precipitated by caustic potassa, by ammonia and carbonate of soda, the precipitate being green and giving blue solutions. Sulphureted hydrogen gives, even in very acid solutions, a brown precipitate insoluble in sulphide of ammonium. Before the blowpipe, in an oxidizing flame, borax gives a green glass which becomes blue on cooling.

NEW ELECTRIC CURRENT REGULATOR.—M. Hospitalier, a French engineer, has invented a new apparatus, which is composed of a resistance bobbin, formed of insulated wire wound on in a single layer, and having each turn stripped of its insulating covering for about 0.4 of an inch at the same spot; a curved lever, controlled by an electro-magnet at one end and by an adjustable spring on the other. This lever moves forward or backward on the bare portion of the bobbin if the current weakens or strengthens, until the resistance is adjusted by the decreased or increased number of turns in the circuit, and equilibrium is produced. The value of an apparatus of this kind for regulating the motion of dynamo-electric machines is great, as much of their utility depends upon steadiness of motion.

The Mineralogical Resources of New Zealand.

In the way of mineral wealth New Zealand is particularly rich, and promises ere many years have passed to compete in the markets of the world with her coal, steel and iron. The mining world was lately not a little startled by a statement that was circulated through the papers to the effect that the New Zealand government had asked for tenders for the supply of 100,000 tons of steel rails to be manufactured in New Zealand of colonial ores. There are vast resources of coal and iron in that country, and the only difficulty encountered in producing for such an order is the want of skilled labor. Dr. Hector, the Government geologist, reporting on these resources, says:—"Extensive deposits of ironstone are to be found in various parts of the colony, and especially would I notice one which I visited at Para Para, near Collingwood, Province of Nelson. I was surprised to find such a large amount of ironstone lying in each huge blocks upon the surface of the ground as I saw in that district. The out-crop of this deposit has already been traced over an area of from two to four square miles. The estimate I formed was that over 15,000,000 of tons of ore were visible upon the surface, without delving into the bowels of the earth at all. Practically, this area appears to be almost inexhaustible. From the analysis and smelting which have been made both at Melbourne and Dunedin, this ore has been found to yield upon the average 50% of pure hematite iron." This Para Para ironstone field is only one of many such districts that remain to be opened out in New Zealand, and in close proximity to it are valuable coal seams, and also an unlimited supply of limestone, so that there appears to be every requisite for the manufacture of iron and steel. Before leaving the subject of iron, we may just briefly refer to another source of supply of the raw material, and although it is not yet a commercial success, there appears to be every probability of that problem being solved at no very distant date. This is the huge deposit to be found on the seashores in certain districts closely amalgamated with the sand. The sea apparently sweeps over rich veins of ironstone, for each receding tide leaves behind it a large contribution to the already monster hillocks of sand and iron that have been piled up on the foreshores for ages past. The high specific gravity of this combination is strongly apparent when a handful is lifted and allowed to filter through the fingers, and an analysis has shown that the combination contains no less than 70% of metal. The smelting of this ore has not, however, been as yet a commercial success, but with such valuable deposits lying on the surface of the earth all over the district ready to the hand, little surprise need be experienced at the fact that very little has been done in the way of experiments in order to solve that problem and to give those seashore deposits a rich commercial value. As it is, the experiments that have been made have discovered that metal produced from this source is most excellent for the manufacture of edged tools and all kinds of whitework.

As to the coal deposits, there are seams from two feet up to no less than 54 feet in thickness, of coal of the best quality, and which can be used for all the purposes of manufacturing, steam, gas, and domestic uses, whilst the area appears to promise almost unlimited quantities. Thus, the Waingeri coal field is estimated at 16 square miles, whilst the Haurangi is estimated to contain 100,000,000 tons, and numbers of fields equally as extensive as these have not been opened out yet. Dr. Hector, reporting to the Government, says the Green Island coal field extends over 40 square miles, and is connected with one of the main lines of railway by a short tramway. It is worked on the room and rance system, the seams being from 16 to 19½ feet in thickness, and the coal a brown sort very useful for manufacturing purposes. He also states that the Small Buller coal field contains upwards of 100,000,000 tons, and the seam in this mine is 18 feet thick, of splendid coal, adapted either for manufacturing, steam, or domestic purposes. This Small Buller mine has been opened about four or five years, but has not been much worked yet on account of the scarcity of labor, and also the high rate of wages paid in the district. Coal also extends over a very wide area in Auckland province, and a report recently made concludes as follows: "Coal appears to have been scattered pretty plentifully throughout the colony, as I have met with it in Otago, Canterbury, Nelson, Westland, Auckland, and other parts of the colony. Besides these, the mineral products of New Zealand are gold, silver, copper, lead, mercury, plumbago and sulphur, the latter being found in very large quantities. As an experiment, some 50 capable workmen have just been selected in the mining districts of the mother country, and are about to be conveyed to the colony by the New Zealand government. A good supply of labor would undoubtedly secure the opening up of many of the rich coal and iron districts of the country, and with the Australian ports within five days' sail of New Zealand, and San Francisco, and the Indian, the Chinese and Japanese ports also within easy reach, there appears to be not the slightest doubt that a good market can be found for the produce.—*Colliery Guardian*.

THE ENGINEER.

A Railroad Across Sahara.

To carry out the proposition of M. De Freycinet, the French Minister of Public Works, a commission of experts has been appointed to study and report upon the practicability of building a railroad through Sahara, between Algeria and Soudan.

Considering simply the length of road required, this project is at once seen to be prodigious in scope. Algeria's system of railway runs westerly from the capital through the northern part of the province in a direction generally parallel with the Mediterranean coast; it scuds out no branch south of the Jebel-Tedla or Atlas mountain chain, so that the new route would practically require construction over nearly the whole distance between Algiers and Timbuctoo, which latter city is at the northern frontier of Soudan, on a tributary of the Joliba or Niger. This distance, as the bird flies, is fully 14,000 miles. But it is also desired to connect Algeria by rail with the French colonial possessions at Senegal, on the Atlantic coast. Now, from Timbuctoo southwesterly to Senegal, in an air line, is upwards of 1,000 miles. The total shortest distance, therefore, would be about 2,500 miles. And since, after reaching Timbuctoo, it is almost certain that the railroad would either wind upward through the valley of the Niger, which is fertile, and has considerable population, or else would move southeasterly down that river before turning and striking off westerly to Senegal, it is clear enough that the road would be over 3,000 miles long. The estimated cost is about \$100,000,000.

IMPROVEMENT OF THE HARBOR OF HONFLEUR.

The harbor of Honfleur consists of an outer harbor, or tide-harbor, having an area of close upon 10 acres, and of three tidal basins. The west basin has a surface of 107,640 feet, a length of 426 feet, with an average width of 256 feet. The quays, which are built of stone, have a united length of 4,986 feet. The entrance to this basin is 125 feet wide. The middle basin is hexagonal in shape, with an area of 43,020 feet; the surrounding quays measuring 1,312 feet in length. The entrance to this basin is nearly 40 feet wide. The east basin has a rectangular form, 975 feet by 234; its quays are 3,015 feet in length, and its entrance is 54 feet wide. The trade of the harbor of Honfleur, which is continually increasing, consists chiefly of the importation of timber from the north, pig-iron and coal, and of the exportation of agricultural produce for use in England. Now, including the quays of the outer harbor, Honfleur possesses only 7,218 feet of quays which vessels can come alongside of, and 38,063 square feet of wharfage available for the loading and unloading of merchandise. It is proposed to remedy this insufficiency of the existing arrangements by the construction of a fourth basin. The new basin will have a length of 1,312 feet, and its least width will be 196 feet. Its bottom will be on a level with that of the entrance to the east basin, with which it will communicate by means of an entrance having the same depth, and a width of 42 feet. The new basin will be effectually protected from the influence of silting up, by surrounding it with a dam raised from 7 inches to several feet above the level of the highest tides, and having a width at the top of 16 ft. This dam which will be connected by slopes to the adjoining ground, will facilitate the hauling alongside of vessels; its inner core will be constructed of earth dug from the excavation of the basin. The cost of the works is estimated at \$100,000. One result of the construction of this new tidal basin would, it is anticipated, by providing sufficient wharfage in the harbor, lead to a considerable increase in the importation of timber from the north into the port of Honfleur.

ANOTHER RAILWAY BRIDGE FOR NIAGARA RIVER.—In 1849 the Lewiston Suspension Bridge Company and the Queenston Suspension Bridge Company were organized, the first on this side and the second on the Canada side of the Niagara river. They built a highway suspension bridge at Lewiston, and maintained it for some time. It blew over one day and was never repaired. The ruins of the structure still remain in the form of masonry on each side of the river, and one cable still suspended. The Oswego *Palladium* says that the Rome, Watertown and Ogdensburg and the Great Western (Canada) railway companies have bought the stock of the old companies above named and formed a company with \$1,000,000 capital to build a bridge at Lewiston. The work will be begun immediately. The bridge will be one of the finest of the kind in the world. The river at the point to be crossed is 600 feet wide. The bridge will be a steel truss structure of one span, and will be a railroad and highway bridge. The object of the parties in interest is to accommodate the local trade of the Rome, Watertown and Ogdensburg road and that of northern New England and the West.

A COMMISSION of French manufacturers and engineers has been named by the Societe de l'Industrie Minérale, with the object of thoroughly studying and comparing the different processes for dephosphorizing iron, and of reporting on their respective merits and costs.

USEFUL INFORMATION.

Chemical Tests.

We here give a list of the substances used for chemical tests, called "reagents," most commonly used for ordinary purposes, and add to each a few lines in regard to their use.

1. *Distilled Water* (formula, H₂O).—In most cases pure rain water may be substituted. It is chiefly used for dissolving such solids as are soluble in water, in order to prepare them for the test.

2. *Ether* (formula, C₄H₁₀O).—Chiefly used for extracting fatty ingredients from a given compound. It is also used to detect and isolate bromine.

3. *Alcohol* (formula, C₄H₁₀O₂).—Used as a solvent for extracting certain substances not soluble in water. It will also precipitate substances which have been dissolved in water and are not soluble in alcohol.

Sulphuric Acid (formula, SO₃HO).—Used as a solvent for many metallic substances, forming with them sulphates. Also a special test for barium, strontium and lead compounds, producing in these solutions a white precipitate.

5. *Nitric Acid* (formula, NO₃HO).—A more general solvent for metals, except the noble ones, among which it only dissolves silver. It is also a powerful oxidizing agent.

6. *Hydrochloric Acid* (formula, HCl).—Also a solvent for many metals, and a special test for solutions of silver, mercury, and lead, with which it produces a white precipitate. Its vapor forms a white chloride with ammoniacal gas.

7. *Nitro-Hydrochloric Acid* (*Aqua Regia*).—The only acid that will dissolve gold and platinum, and decompose certain metallic sulphides.

8. *Oxalic Acid* (formula, C₂O₃HO).—Its solution a special test for lime. It produces a precipitate or at least milkiness in solutions of lime compounds.

9. *Tartaric Acid* (formula, C₄H₄O₁₀).—A special test for potash. It produces in potash solutions a crystalline formation of cream of tartar, and is used to prevent the precipitation of certain metallic oxides by alkalis.

10. *Baryta, Caustic, Nitrate, Acetic and Chloride*.—Special tests for sulphuric acid or sulphates, producing a white precipitate in their solutions. The caustic baryta produces a white precipitate in magnesia solutions.

11. *Potassa, Caustic* (K O) is used as a solvent of some and as a precipitant of other solutions; separates some oxides from others, and drives free ammonia out of all its salts, so that it can be detected by the smell.

12. *Carbonate of Potash* (KO, CO₂) is used as a precipitant, and for the decomposition of many insoluble salts, especially organic with metallic bases.

13. *Sulphate of Potash* (KO, SO₃) is used to precipitate baryta and strontia, if the use of free sulphuric acid is objectionable.

14. *Cyanide of Potassium* (KCy) is used to separate cobalt from nickel, and to reduce arsenic by heat, but mostly used as a flux for the blow-pipe.

15. *Phosphate of Soda* (2NaO, PO₅) is a test for alkaline earths in general, especially magnesia.

16. *Phosphate of Soda and Ammonia* (NaO, NH₄O, PO₅, HO).—It is the most important blow-pipe reagent, as it fuses almost every chemical compound, hence its name of "micro-cosmic salt."

A NOVEL GAS GENERATOR.—A novel arrangement for the manufacture of illuminating gas from gasoline is thus described: The reservoir for the gasoline is placed at a considerable elevation above the stationary burners on the walls. The gas, which is generated by simple evaporation, being heavier or having greater specific gravity than the atmosphere, is driven down by the latter through the orifice at the base of the reservoir, into the gas pipes, and conducted to the point where it is required for illumination. The gas may, it is said, be made at a cost not exceeding one-half the cost of coal gas. While the invention has some merit, it also has some drawbacks which cannot be easily overcome. In order to insure its successful operation it must be located in a warm room, else evaporation will not go on rapid enough to supply the gas needed to support combustion.

BISMUTH CRYSTALS.—Crystals from bismuth may be obtained by melting two to four pounds of the metal in a hemispherical iron ladle, allowing it to cool slowly until a crust is formed on the surface, then breaking this with a wire and pouring out quickly the still fluid metal from within. This yields, if not always large crystals, at least faces, from which project the corners of numberless cubes. Fine large crystals, with beautiful stair-like arrangement, can be obtained only by making the bismuth chemically pure, which is a tedious operation.

BEST SILKWORM TO REAR.—Dr. Wallace, an authority on silkworm culture, said at a recent meeting of the London Entomological Society, that he had experimented with nearly every kind of silkworm which had been introduced into Europe, and that he had come to the conclusion that the only one which would pay to cultivate in England, was the *Bombyx mori*. He claims that the product of *Bombyx mori* is a superior article to any other.

GELATINE.—Gelatin, it is said, has a peculiar action on gum; if gum be added to gelatin, and the mixture sensitized with ammoniacal potassium bichromate, the behavior of the latter substance is very little altered by the addition of the former. Its solubility in hot water is somewhat increased, and to obtain the same degree of insolubility for the image as with pure gelatin the exposure must be longer. But if the mixture be acidulated with acetic acid, the film after exposure and desiccation is less soluble than one consisting of chromated gelatin only with acetic acid. Gum, therefore, renders an acid solution of gelatin less soluble, and the reason for this is believed to be that glutine and arabinic acid form a compound solid only with difficulty. Borax thickens a gelatin solution, and the alkaline reaction of the same substance tends to render the chromated gelatin more insoluble. Calcium nitrate gives to gum an enormous power of adhesiveness.

RAILROAD EARNINGS.—The gross earnings of all the railroads of the country for the last year were \$490,103,361, against \$472,909,272 for the preceding year. What is remarkable in looking over the figures which make up these totals is the large part contributed by the Western roads. On this point *Poor's Manual* (advance sheets) says: "The gross earnings of the railroads of the Western States were \$209,852,275, against \$193,204,516 for 1877; net earnings, \$77,958,220, against \$66,085,253 for 1877. The dividends paid amounted to \$19,341,222, against \$14,556,462 for 1877. The earnings from freight, mails, etc., were \$160,856,795, and from passengers, \$49,995,480."

PHOTOGRAPHIC PATTERNS.—One of the silk manufacturing firms of Lyons, France, are introducing the production of photograph impressions on stuffs. They sent to a recent meeting of the Photographic Society several pieces of silk with a variety of photographic pictures printed thereon, including, among others, a number of large medallions representing pictures of the old masters. The length of the specimens thus exhibited is stated as being no less than 131 feet. The process by which they are produced is not given, but it is believed, says the *Commercial Bulletin*, that the prints are made with salts of silver.

NAIL TERMS.—Many persons are puzzled to understand what the terms "fourpenny," "sixpenny," and "tenpenny" mean as applied to nails. "Fourpenny" means four pounds to the thousand nails, or "sixpenny" means six pounds to the thousand, and so on. It is an old English term, and meant at first "ten pound" nails (the thousand being understood), but the old English clipped it to "tenpenny," and from that it degenerated until "penny" was substituted for "pounds." When a thousand nails weigh less than one pound they are called tacks, brads, etc., and are reckoned by ounce.

RESISTANCE OF ELECTRIC ARC.—According to the *Journal of Franklin Institute*, the relations existing between arc resistance and current strength and illuminating power, are, within a certain range of conditions, apparently expressed by the following laws: 1. In arcs of equal lengths the resistances are inversely proportional to the current strengths. 2. The illuminating power of an arc is approximately proportional to the current traversing it. 3. In arcs of equal length the total energy given out is proportional to the current strength.

GOOD HEALTH.

Poisoning by Strychnine.

A recent case of poisoning by strychnine in San Francisco, where the patient was well and rational for a long time after the reception of the deadly drug, and conversed pleasantly with his physician, recalls a remedy which is said to be so well known and successful that where life remains the effect of the strychnine may be entirely obliterated and its deadly action destroyed. We allude to chloroform. The effect of strychnine on the system is to produce a contraction of the great nerve centers, or ganglia, and bring about paralysis. Acting directly for these points, it reaches the brain and destroys its vitality by its enormous contractile power upon the system. In case of poisoning by so doing, the contraction is made manifest by the "twitching" of the muscles, the mouth is drawn in different shapes, and the patient then has generally been said to be so effectually under the influence of the drug that he cannot be saved. It is agreed, however, that there need never be a fatal case of poisoning by this death-producing element, and that as long as any sign of life remain a cure can be effected. Chloroform is administered in sufficient quantities to keep the patient under its influence. This anesthetic attacks the nerve centers with the same vim as strychnine, but produces a contrary effect, in that it causes a relaxation, and fights the strychnine on its own ground. By allowing the patient to recover from the effect of the chloroform, the "twitchings" of the muscles will be resumed if the strychnine has not been effectually counteracted. In this case, chloroform must be applied again without delay, and kept up as long as the nervous or

spasmodic contractions appear. The remarkable effect of the chloroform is apparent as soon as administered. The contractions and twitchings of the mouth, etc., immediately cease, and do not return as long as the patient is under its influence.

New Use for Coconut Milk.

Dr. George M. Sternberg, Secretary of the National Health Commission, now at Havana, says:

I find that the air of our laboratory is loaded by minute spherical organisms, and contains bacteria not distinguishable from *bacterium termo*. I have made some experiments for testing apparatus designed for the purpose of keeping putrid fluids germ-proof, using for my test the liquor from the interior of an unripe coconut. This liquor possesses properties which will, I believe, make it of great value. It is transparent as water when the nut is not too ripe, is contained in a germ-proof receptacle (the coconut), and when exposed to the air, bacteria and other organisms develop with astonishing rapidity. In my first experiment two portions from the same nut were placed in small beakers, one exposed to the air and the other protected by the glass cover and bell jar (Lister's apparatus), with previous precaution of heating apparatus to 320°. The following morning the portion exposed to the air was milky in appearance and loaded with bacteria large and small, and had upon its surface a pellicle containing the cells of some fungus; the portion under the bell jar was clear as water. I have succeeded in keeping this liquor in quantity for three days in a Florence flask, made germ-proof by heating to 320° Fah., and provided with a cotton germ filter. I have made several good negatives of bacteria developed in coconut liquor for the purpose of testing my lenses and apparatus. I propose to continue the experiments commenced during the ensuing week.

ACTIVITY, NOT ENERGY.—The *Christian Union* thus defines the difference between activity and energy, and suggests wherein a large class of industrious people lack that element which produces success. There are some men whose failure to succeed in life is a problem to others as well as to themselves. They are industrious, prudent, and economical; yet, after a long life of striving, old age finds them still poor. They complain of ill luck. They say that fate is always against them. But the fact is that they miscarry, because they have mistaken mere activity for energy. Confounding two things essentially different, they have supposed that if they were always busy they would be certain to be advancing their fortunes. They have forgotten that misdirected labor is but waste of activity. The person who would succeed is like a marksman firing at a target; if his shots miss the mark they are a waste of powder. So in the great game of life, what a man does must be made to count, or might almost as well have been left undone. Everybody knows some one in his circle of friends, who, though always active, has this want of energy. The distemper, if we may call it such, exhibits itself in various ways. In some cases the man has merely an executive capacity when he should have a directive one—in other language, he makes a capital clerk of himself when he ought to do the thinking of the business. In other cases, what is done is not done either at the right time or in the right way. Energy, correctly understood, is activity proportioned to the end.

MAN'S OCCUPATIONS AND MORTALITY.—The statistics of mortality in Massachusetts since 1843 teach some instructive lessons in regard to the influence of man's occupation on his chances of longevity. We extract a few data showing the average duration of life of various occupations: Gentlemen of leisure, 68 years; farmers, 66; judges, 64; light-house keepers, 63; female nurses, 62; basket makers, 61; pilots, 60; sextons, ship carpenters, bakers and clergymen, 59; professors of colleges, 57; lawyers, 56; physicians, 55; clock and watch makers, sheriffs and policemen, 53; wharfingers and butchers, 51; editors of political papers, 47; peddlers, 46; artists, 44; dress makers, 43; druggists and dentists, 42; musicians and music teachers, 41; saloon keepers, tobaccoists, printers, railroad agents and conductors, 40; milliners, factory girls and domestics, 39; glass-blowers and powder-mill employees, 38; clerks and book-keepers, 36; plumbers and carvers, 35; female school teachers, 32; telegraph operators, 28; brakemen on railroads, 26.—*Manufacturer and Builder*.

GOOD NEWS FOR DYSPPEPTICS.—We have seen, says one of large experience, dyspeptics who suffered untold torments with almost every kind of food; no liquid could be taken without suffering; bread became a burning acid; meat and milk were solid liquid fires, and we have seen their torments pass away and their hunger relieved by lying on the whites of eggs which had been hoiled in bubbling water for 30 minutes. At the end of the week we have given the half yolk of the egg with the white, and upon this diet alone, without fluid of any kind, we have seen them begin to gain flesh and strength, and quiet, refreshing sleep. After weeks of this treatment they have been able, with care, to begin other food. And all this without taking medicine. Hard-boiled eggs are not half so bad as half-boiled ones, and 10 times as easy to digest as raw eggs, even in eggnog.

TABLE OF CONTENTS.

EDITORIALS.—The Prospector and His Rewards; Brown's Caloric Engine; Resistance of Metals to Repeated Shocks, 129. The Week; Improved Mining Prospects; Rights of Shareholders, 136. Science and Industry; Death of R. B. Woodward; Notices [of Recent Patents, 140.

ILLUSTRATIONS.—The Brown Caloric Engine, 129. Map of Lake District, Mono County, Cal., 137. CORRESPONDENCE.—Concrete as a Substitute for Stone in California; Eureka and Its Mines; Kern County Mines, 130. Mono County Mines, 136.

MECHANICAL PROGRESS.—Paving Streets by Steam; Horograph; Heating Soldering Irons; New Elevator; Automatic Clock; A Novel and Swift Vessel; Automatic Sand-brake for Railways; Some Old Patents; 131.

SCIENTIFIC PROGRESS.—Sulphides as Fuel; Reproducing Drawings; Ancient Human Skull; Contact of Micrometer; Giving flax the appearance of Silk; A New Magnetometer; Single Story Mills, 131.

MINING STOCK MARKET.—Sales of the San Francisco, California, and Pacific Stock Boards; Notices of Assessments, Meetings and Dividends, 132.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon and Utah, 133-140.

MISCELLANEOUS.—Magnetic Strains in Iron. Agricultural Machinery at the Mechanics' Fair; Norwegian; New Electric Current Regulator; The Mineralogical Resources of New Zealand, 134.

THE ENGINEER.—A Railroad across Sahara; Improvement of the Harbor of Houfleur; Another Railway Bridge for Niagara River, 135.

USEFUL INFORMATION.—Chemical Tests; A Novel Gas Generator; Bismuth Crystals; Best Silkworm to Rear; Gelatine; Railroad Earnings; Photographic Patterns; Nail Terms; Resistance of Electric Arc, 135.

GOOD HEALTH.—Poisoning by Strychnine; New Use for Cocoon Milk; Activity, not Energy; Man's Occupations and Mortality; Good News for Dyspeptics, 135.

NEWS IN BRIEF on page 141 and other pages.

Business Announcements.

To Quartz Mine Owners, Clarence Brooks, S. F. The Americanized Arastra, Almarin B. Paul, S. F. The Advertisment, L. Brinkman, San Quentin, Cal.

The Week.

From all parts of the country come the most encouraging reports concerning the mining prospects. The condition of California to-day, in regard to its precious metal supply, would seem not to be far behind its palmiest days, when gold was to be had for the picking up. Old claims have been rejuvenated, new and rich discoveries have been made, and the immense quantity of waste on the Bear and Yuba rivers promises to yield a large return by the aid of new processes for utilizing the waste. Mono county mines may be said to be a source of permanent wealth. A general prospecting for precious minerals seems to be inaugurated, and judging from the results already attained, the future is the most encouraging. Oregon has time outside of her agricultural and timber features to find precious minerals and wash out gold from gravel claims. The Boise basin in Idaho is turning out rich ore from its mines, and general activity prevails there. Washington Territory and Montana are also adding to this world's supply of bullion; while, if all accounts are true, Utah and Arizona are daily laying bare enormous wealth. The San Juan region of Colorado possesses mineral wealth which is being developed and made known by interesting accounts.

We are obliged to say that the general appearance of this mining business is better than that of the industrial arts. There has been some movement in machinery, but not sufficient to warrant us in comparing it with the activity displayed in mining researches. The Mechanics' fair now open in this city is filled with interesting and valuable exhibits of machinery and processes, which attract much attention and interest.

PERSONAL.—Publishers and others will learn something to their advantage by communicating with us before having any business transactions with C. Stephenson, lately connected with newspapers in Auburn, Elko, Omaha, Chicago, New York, etc.

Improved Mining Prospects.

There is reason to say that the element of encouragement predominates in the mining prospects of this slope. From reliable information, we are impressed with the idea that a period of healthy activity has opened upon our important interests, and that systematic prospecting has reaped its fruits in the developments made in various quarters. Many old and partially abandoned claims have been re-prospected, and resulted in valuable discoveries that have justified the investment of capital. The old Croesus mine in Placer county, now owned by Wm. Gwin, has developed a ledge of from three to seven feet in thickness, very rich in sulphurets. At Coulterville, in Mariposa county, a ledge about to be abandoned has by careful prospecting developed into a valuable ledge, rich in sulphurets. New capital is being put into the old claims of Inyo county, near Resting Springs, and rich ore is being taken out. Excellent quartz ledges have been struck in Sierra county, back of the Reess mine. The hydraulic mines have been paying satisfactorily, so far as the results can be obtained. Many of them have shut down to clean up and wait for winter rains, while others are still working advantageously in localities where a constant supply of water can be obtained; particularly several in Nevada county are making large returns of precious metals. At the Henrietta Gravel claim, above Oroville in Butte Co., an increasing yield of coarse gold, for which this claim has been noted, has justified this putting in of a dredger and improved mechanical appliances.

The gravel mines of Toulumna county are yielding their quota of precious metals, while in Sacramento county the old placer claims about Folsom are increasing their returns, having an abundance of water supplied by the Natoma Co. ditch.

A flume is being put in at Bear river, in Placer and Nevada counties, to work the tailings along that river, which have proved to be very valuable. The quantity of tailings here and up the Yuba river is immense, and new processes have enabled the utilization of what before was considered waste.

Beach mining, or working up the black sand along the sea coast, is increasing by reason of a new blanket sluice of peculiar form, which obviates the difficulties heretofore encountered in separating the gold from the sand. Considerable of this kind of mining is being done with profit all along the coast from Santa Barbara to the Oregon line.

Recent discoveries of gold and silver-bearing rock in Fresno county have directed attention to that quarter. The topography of the county is favorable, and good wagon roads are about to be constructed. With a rich soil and an inexhaustible supply of water, this county bids fair to become an important one in respect to precious metals and agriculture.

In Mono county the magnitude and extent of the mining interests have begun to be realized, and the preparations made to bring out this vast supply of precious minerals, indicate a brilliant and solid future for this county. Every where in California new and rich discoveries have been recently made, and improved processes have enabled capital to realize from the immense waste of former years.

We do not doubt that the resources of California are, to a certain extent, yet unknown and unprospected. This results of careful examination even in old localities that have been supposed to be worked out is very encouraging for the further prospecting in new regions outside of the beaten track. From the mountain tops to the sand washed up by the ocean on this beach, the precious metals are being taken out with profit. Surely in view of these facts, condensed as they are, we are justified in saying, that the mining prospects of this State are flattering. And that so far from feeling discouraged, we have every reason to congratulate ourselves upon the arrival of a new era in our mining prospects, which is proving itself to be as progressive as are the mechanical appliances which have partially enabled this condition of things to be accomplished.

FINE SPECIMENS.—We have been shown by Mr. Thos. Mootry, Jr., some handsome and neat specimens of ore from the Gold Hill mine, on Granite creek, near Quartzburg, Boise county, Idaho. We gave a detailed description of the mine and works some time since, so it is not necessary to repeat it. It has been worked since 1863. The company now own some 7,000 feet of ground, and have a 25-stamp mill, four pans, two settlers, and five concentrators, with a 60 horse-power engine. The 200 square feet of plates in front of battines, are silvered by what is claimed to be a peculiar process, which enables them to catch the finest ore. They are now working through a 250-foot shaft, at the bottom of which its main level extends 600 feet each way. The ledge is stated by Mr. Mootry to be from 4 to 10 feet wide. It is decomposed and contains strata with pockets of specimen ore, such as has been shown to us. This is very rich and beautiful. The owners are T. Mootry, Jr., D. and W. A. Coughanour, the latter being Superintendent. On Canyon creek, three miles off, are the Belshazzar, Ebenezer, and Mountain Chief mines, all turning out good ore, which is crushed at the Gold Hill mill.

Rights of Stockholders.

This case of Erwin Davis, plaintiff and respondent, vs. the Flagstaff Silver Mining Co., (limited) et al., defendants and appellants, recently decided in the Supreme Court of Utah by Associate Justice Boreman, has a wider application than is covered by the case at bar. Like other decisions of importance involving general principles, it would seem likely to be a precedent in cases of abuses of a similar nature. There can be no doubt that our courts are gradually raising their standard of adjudication to meet the requirements of equity, and the constitutional privileges accorded to every man in regard to his property, and right to be protected from whatever is detrimental to those rights.

It appears from Judge Boreman's decision that "The appellant, the Flagstaff company, was incorporated in England, to acquire, hold, and operate mining and smelting properties in Utah. The respondent sued the company, alleging the purchase of ores from it, and the non-delivery thereof; also, that he had advanced money to said company, and that contract was entered into by and between the company and himself, whereby to acquire a lien upon the properties of the said company in Utah; and he asked the enforcements of said contract, and that a receiver be appointed. The other defendants were made parties because they were supposed to hold liens against the property of the said company."

The court below appointed a receiver as prayed, and ordered the surrendering the property to the receiver, at the same time enjoining the parties from interfering with the receiver in his management of the mine. The judgment fixed the priority of the liens, and ordered the receiver to pay out thereon, and to respondent sums amounting to a total of nearly \$290,000 and interest. This judgment and the order of the court overruling the motion of the company for a new trial was appealed from. It appears that the respondents, by arrangement with the directors of the said company, had loaned the company very large sums of money, which were to a great extent, if not entirely, used in paying dividends. Subsequently, the character of these loans was sought to be changed, and thus was created what are now offered as "ore contracts." And, thereafter, this alleged contract of December 13th, 1873, was entered into by said company, through its directors, and by said respondent in person. This alleged contract of December 13th, 1873, called exhibit "A," was based upon the ore contracts and directed their payment.

"It seems clear that there was no affirmative action of the stockholders ratifying or approving either the loans, the ore contracts, or the contract of December 13th, 1873. Whatever there was in their conduct supposed to bear such a construction was of a negative character. But, in such matters, a corporation must be judged by its acts, and not by its failures to act. It cannot be said to approve that which it simply failed to disapprove by express words.

"A corporation has no powers but such as are granted either in express terms or by direct and necessary implication. This company had no power granted to it to make loans of money, except under special limitations as designated in Section 20 of the 'Articles of Association' of said company. The loans were far in excess of the amounts authorized. The use of the money to pay dividends was in violation of the acts of Parliament, called the companies' acts. By these acts, this corporation is prohibited from declaring any dividends, 'except out of the profits arising from the business of the company.' Dividends paid out of borrowed money were not paid out of 'profits.'

"It could not be said that respondent was an innocent party and should not be held responsible for any exercise by the company of powers not granted or of powers prohibited. Actual knowledge of the want of authority in the company is not necessary to be shown. In dealing with the company as respondent did—in being a party to an executing contract—he must see to it that the company has the powers it claims to have. In the instance before us, we have no doubt that the respondent was fully aware of the corporate powers of the company. He was one of the incorporators of the company, and one of the first directors. He owned and bought and sold large amounts of its stocks. He was a stock broker and a manipulator of stocks. He went to London with letters that gave him 'a good position' (to use his own language), and he says that, 'in London, the way of operating is very different from here—decidedly old fogish. They did not understand bulls and bears on the stock exchange. A man would go to a bear a thousand or two pounds there, and make as much disturbances about that as a man in America would a million.' It was right in the line of his business to know the general powers of these stock corporations. The large dividends from the borrowed money increased the market value of the stocks; this public supposing that the company was doing a legitimate business, and paying dividends out of 'profits,' and such people 'did not understand bulls and bears on the stock exchange.' A shrewd manipulator of stocks could afford to run the risk of losing money loaned to a company to be used to pay dividends, when he knew that he could receive it all back, and much more too, by the sudden rise in the price of stocks.

"The evidence shows that the directors at

that time were acting in entire harmony with this respondent, and willing always to comply with his wishes. The respondent did not propose to cross the money advanced, and hence the claims were put into the shape of 'ore contract.' A change of shape did not change the substance, however. Being based upon fraudulent and void loans, they were necessarily also fraudulent and void."

Dividends from "Anticipated Profits."

"But, let us assume that no loans ever were made, and the ore contracts were original, and based upon prior transactions between the parties. The receipt of forward payment for ores to be delivered in future, as specified in these contracts, was beyond the powers of the corporation. The company has no grant of authority to thus bulk its expected productions, and involve the company to its ruin by subsequent inability to comply with the terms of this contract. Money arising from such forward payments for ores could not legally be used to pay dividends. Such money was not 'profit arising from the business of the company.' This money might be termed anticipated profits, but we nowhere find any authority for the company declaring dividends out of any profits; except such as are realized out of the business—'arising out of this business, of the company.' And it is against public policy to allow corporations to thus deal so as to deceive and defraud the people. An unscrupulous director or company might have no ores, and yet sell ores for 10, 20 or more years ahead of the production thereof, and use the money thus acquired in declaring one or two dividends of enormous size. Those knowing the inside workings of the company could sell off all their stocks at enormous profits, and leave the company bankrupted, and in the hands of those who were deceived and defrauded into buying the stocks. Courts cannot look with any favor upon claims for such powers in corporations.

"We, for the reasons stated, do not think that that respondent has a claim upon the company for the enforcement of this contract, Exhibit 'A,' sued upon, nor is he entitled to damages for its breach or non-fulfillment.

"The main feature of the judgment in this case is that of appointing a receiver. Everything else in it is made subservient to this one matter—is secondary to it.

"The judgment in this case is for the appointment of a receiver, and for nothing else except that which is incidental thereto. He is appointed, and directed to carry into execution a certain contract. As that cannot be done according to the terms of the contract, he is directed to pay money instead of ores. The defendants are enjoined from interfering with the receiver, and required to deliver certain property to him. The judgment, being solely for the appointment of a receiver and for matters incidental thereto, and not being made in compliance with either provision of the statute, was improper.

"The judgment and order of the court, below is reversed with costs, and the cause is dismissed.

"Schaeffer, C. J., dissents."

Mono County Mines.

[Written for the Press by J. W. A. Wright.]

Lake District, Mammoth and Pine Cities.

The wanderings of your correspondent in these parts having taken him to the new mining districts of eastern Fresno, as already described, he concluded to make a short visit to the much talked of Mammoth mines of Mono county, and its adjoining ledges, as they were but five or six miles distant. I hope the facts and figures there learned may be of some interest and use to your readers:

These ledges comprise what is now known as Lake District,

So called from the chain of five or more small lakes which form the sources of Owens river. No mining region on the Pacific coast is more favorably located for supplies of wood and water, or for the ready drainage of its mines to a great depth than is this new and extensive mineral belt; nor has any a more picturesque location in the midst of wild, grand, and varied mountain scenery. The extent of its mineral belt is about four miles long and a little less than a mile wide, so far as prospected.

When you reach the highest point in Pumice-stone Gap, on the divide between Fresno and Mono counties, and at an altitude of 10,350 feet, this fine and extensive view is spread out before you. Immediately opposite and not more than a mile distant in a direct line, is Mineral hill, along the top and precipitous red and gray sides of which all the ledges of this district are found. Its highest point towers fully 1,000 feet or more above you. In the gorge at your feet, from 500 to 1,000 feet below you, are the clear, cold lakes and cascaded streams connecting them, which form the head waters of Owens river. Just east of the middle lakes and immediately under the western cliffs of Mineral hill, is Pine City, with its 30 frames and log buildings, between 9,800 and 10,000 feet above the sea, and a population of 100 or more. About a half a mile beyond and along the northern base of Mineral hill, in a narrow depression descending eastward between that and a large knoll, formed chiefly by the agency of ancient glaciers, is Mammoth City.

Its 125 new frame houses extend for about a

quarter of a mile on both sides of Mammoth avenue, a street with good width of some 80 feet. Its permanent population is estimated at some 300 or 400, though this Spring there were said to be 1,000 or 1,500 people in and around town, most of whom were out prospecting in July. Its altitude at a central point is 9,700 feet. Immediately below Mammoth City, eastward, are the 20-stamp mill, the offices, stable, and lodging houses of the Mammoth mining company; also, the large store and express office of L. Wallerstein & Co., and the office of the Don Quixote mining company. Their altitude is about 9,500 feet. The mill is connected with the mine by a tramway over 3,500 feet long. About a mile northeast, and at several hundred feet less altitude, is Mineral park, where, since May last

McFarland and Fraser's Saw-Mill

Had cut up to July 650,000 feet of lumber, and their shingle mill had turned out 400,000 shingles. It is located in a dense forest of large-sized firs and yellow pines, with which all that region abounds. Higher up, even to altitudes of 11,000 feet, are heavy belts of tamarack, or as it is called in parts of Nevada, "hack-matack."

42 feet; the next longest is 36 feet. Then in succession, at irregular intervals, according to convenience in working, are cuts of 28, 18, and 23 feet. Mr. Cross has exposed here so large a mass of ore that he assured us he could take out daily, if necessary, 500 tons of ore, though they do not expect to crush more than 120 tons per day, when certain additions are made to the mill and its power. (3) Below this a third tunnel is finished 160 feet, some 200 feet more being required to reach the ledge. (4) A still lower tunnel is completed 560 feet, at least 240 feet more being necessary to strike the ledge. (5) At a point farther east another tunnel is projected, which, according to estimate, is to reach the ledge with a length of 2,000 feet, and at a depth below the higher outcroppings of 1,800 feet.

Originally, Mammoth was considered a silver mine, and its mill was rigged accordingly. Results prove that on an average only about 25% of its yield is silver. Consequently the company is now making

Important Changes and Additions

In its mill, heretofore they have relied on water-power alone, using Knight's hurdy-gurdy wheel. But this giving only 65 horse-

power, as they are expected to be in September. Part of the large ledge is certainly low grade ore averaging \$20 or less. Mr. Cross gave me the following as a fair example of the yield of some of their good ore. Amount reduced 44 tons. Yield from the pulp \$53 per ton. He cleaned up the mortars, and got a bar of hulsion 180 ounces at \$13 per ounce. But while the Mammoth is the only mine in the Lake district in which regular work is going on, except as prospecting, and is the one that has given reputation to the district, it is

Not the First Discovered Nor the Only Ledge

There. The first ledge discovered there was the Alpha near Pine City. It was located June 19th, 1877, by Messrs. Lowe, Parker, Smith and Martin. A tunnel 185 feet has been run into it, having struck some small ledges, one 12 feet wide, but has not yet reached the main ledge, which is supposed to be 30 feet further. Its assays are reported to have ranged from \$4 to \$852.69, half gold, half silver. Next the northern extension of it, called the Jordan was located. In it a shaft has been sunk 15 feet. The third location was the south extension of Alpha, known as the North Star.

It is in the main correct. Merely observe that Lake City is now called Pine City, and ledges not there named can be located by the above description.

We shall close this letter with some account of The Work Done and Assays

In some of these claims. A. Caldwell, Superintendent of the True Blue, informs me that their prospecting shaft is down 36 feet, that an assay shows \$15 free gold, and the deeper they go the ore improves. Vein over 14 feet wide. Tunnel in 20 feet from eastward projected to strike ledge 600 feet below surface. He informs me also, that a vein 500 feet eastward of said shaft in the company's ground, shows 25 feet of ore that will average \$80, but has assayed as high as \$553, chiefly silver. In Silveropolis shaft is down 12 feet; tunnel 35 feet in Crescent City, their prospects good as adjoining claims.

F. C. Farnham, Superintendent of the Monte Christo, informs me that they began work there last April. Their shaft is down 80 feet, and 75 feet of crosscuts have been made. Ledge averages 12 feet in width, good paying quartz; yield about 40% gold, which is free, the silver being sulphurets. In the Head Light, which

MAP OF LAKE DISTRICT, MONO COUNTY, CALIFORNIA.

The ledges and tunnels of Mammoth Mine

are on the north face of Mineral hill, immediately above Mammoth City. Its principal stockholders and directors are as follows: Thos. Bell, President; Geo. W. Grayson, W. W. Traylor, Archie Borland, Sol Heydenfelt; and Secretary, A. W. Rose, Jr. Mr. James Cross, its careful and energetic superintendent, kindly gave your correspondent every facility for examining the mine and its works. He accompanied a party of us up the incline and through the main or middle tunnel, where most of the work was then going on. From him and from personal observations the following facts were learned: Four tunnels have already been begun, and a fifth is projected. (1) Along the outcroppings, at an altitude of about 10,500 feet, is the upper tunnel in 157 feet, but not now worked. (2) Below this some 250 feet is what is known as the middle tunnel. This was completed about 500 feet, with a lateral drift for 300 feet. From this tunnel and its various branches all the ore is now taken. Our party carefully prospected every portion of it. Though five long crosscuts were already made, the true width of this very extensive and uniform ledge is not yet known. The longest crosscut here is

power, and proving insufficient, they are now putting in a steam engine 24x48, or as large as that in the Consolidated Virginia, the largest size for milling purposes on this coast. They are also increasing their stamps to 40, adding an extra rock-breaker and a large air-compressor. A lathe also will be put up soon, and a cupola for casting necessary shoes and dies, and other fixtures. At great expense, strong dams have been made at the lakes to save water enough for all seasons. The long tramway from mine to mill is to be so changed that for the whole length the loaded cars can pull up the empty ones, and the entire structure will be covered with snowsheds, so that they can work all winter in spite of snow 10 or 12 feet deep for several months.

In proof of the confidence of the company and their superintendent in the value of this great ledge, the mill when finished will have cost \$160,000; other structures, roads, etc., about \$100,000 besides.

The Most Valuable Ore

Of the Mammoth is in a seam or chimney five feet wide, passing through the main ledge. This narrow vein is unquestionably very rich in free gold. Little, if any of it has yet been milled. It is reserved until the additions to the mill are

Its southern extensions in regular order towards the southeast are the Last Glimmer, the Ajax, and the Red Cloud or Chrysolite. Between the Jordan and the Mammoth is a claim called the Armstrong. On the next ledge east of the Alpha come, in succession from northwest to southeast, the Big Bonanza, Chief of the Hill and Panther. Next eastward, the Eureka corners at the southwest angle of the Mammoth, and its south extension is the Crescent City. Next east comes in above order to southward the Hutchinson, Foulk, Mammoth, Head Light, Monte Christo, Monticello, Baltic. Still eastward are the Tiger, the Don Quixote, the Wisconsin or True Blue (in dispute), the Great Eastern, the Silveropolis and Denis Kearney. A claim called the Merrimac, between the Monte Christo and Great Eastern, also conflicts with the True Blue. South of Merrimac is the Silverite. Still further southward, are the Black Hiller Geneva and Last Chance. Yet many as are the claims here named, they are not all that are located in this belt. Every space, whether granite, slate or porphyry seems to be located, judging from the monuments in every direction. For convenience of readers the accompanying map is repeated from the MINING AND SCIENTIFIC PRESS of December 28th, 1878.

is under Mr. Cross' management, shaft is over 80 feet, and ore good. John Riordon, who kindly spent a day showing me the various ledges, assures me that assays from his claims, the Eureka and Chief of the Hill, range from \$50 to \$250, some \$10 or \$20 of this being gold. The Merrimac assayed \$15 silver, and \$25 gold from ore 20 feet down, but at 30 feet depth, \$20 silver and \$60 gold. As usual, there are some conflicts about titles, but I learn from W. S. Lilien, U. S. Deputy Surveyor, that the Mammoth and Head Light now have their patents. The True Blue, Don Quixote, Silveropolis, Crescent, and Monte Christo were already surveyed for patents.

The hotel conveniences of Mammoth City provide well for all visitors. The Monumental hotel, of Bunker & Co., is central and very comfortable. Here A. B. Anderson, a California pioneer, so well and favorably known as the genial host in Snelling and Fresno City, looks after the welfare of guests. He kindly accompanied your correspondent on one of his excursions. With other citizens, he takes deep interest in having our State Commissioners furnish their numerous lakes with fish. Why can this not be done?

Fresno Co., Aug. 2d.

DEWEY & CO.

American & Foreign Patent Agents,

OFFICE, 202 SANSOME ST., N. E. COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 202 Sansome St., N. E. corner Pine, S. F.

PATENT**LIFE-SAVING RESPIRATOR**

Prevents Lead Poisoning and Salivation.

INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Mines, Guano Works, White Lead Corroding, Feeding Threshing Machines and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price \$3 each, or \$30 per dozen. Sent post-paid to any address upon receipt of price.

JOHN A. CHURCH,**MINING ENGINEER,**

COLUMBUS, OHIO.

A CARD.

To Parties Interested in Mining and Milling.

Call at J. HENDY'S, N. E. corner of Mission and Fremont Streets, San Francisco, and examine COLEMAN'S PATENT SLUICE. It will save both float and flour Gold. The best system yet devised. No power required to work it. Examine it and judge for yourselves before purchasing elsewhere.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

CAUTION—To Section Chimney Builders.

All chimneys on which joint hands with cement, or its equivalent, are used to make the joint smoke and fire-proof, with rods, clamps, or their substitutes, to brace the chimneys to the buildings, are INFRINGEMENTS on my patents. My patents for sectional chimneys have been sustained in every instance.

J. BROWELL, Pioneer Chimney Builder,
442 Jackson St., S. F., and 1200 Broadway, Oakland

C. C. Bitner's Apparatus for Obtaining Metallic Copper from its Solutions.

Patented March 18th, 1879. Will precipitate with steam in three hours, requiring no machinery to run it. Cost of constructing apparatus, \$75. The old cylinder process takes four hours to precipitate and costs from \$1,200 to \$1,600 to construct, besides the machinery to run it. For right to use my Precipitator address O. O. BITNER, Spenceville, Nevada County, California.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

AN ENGINEER,

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, bolting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The bolting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending hocket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

FRANCIS SMITH & CO.,

Manufacturers of

THE PATENT CHANNEL IRON WHEELBARROWS.

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe.

Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

THE ELKINS

"BOSS" GOLD AMALGAMATOR,

Is the Best, Simplest and Cheapest Amalgamator in Use.

Nothing about it to get out of order or wear out. Weighs only 500 lbs.—heaviest piece weighs 100 lbs. Is automatic in its working. Measures, feeds, screens and passes all material through a large body of quicksilver; then washes and cleans without care or attention. Requires no more power than a large grindstone. Uses water over and over again where water is scarce. All water required can pass through a 3-inch pipe. Capacity, two to four tons per hour. Saves 90% of precious metals. Price, \$250. Pump \$25 extra. Send for circular.

ELKINS & LYNCH,

No. 318 Pine Street, - - SAN FRANCISCO.

STEEL CASTINGS.

From 1-4 to 10,000 lbs. Weight.

True to pattern, sound and solid, of unequalled strength, toughness and durability.

An invaluable substitute for forgings or cast-iron requiring three-fold strength.

Gearing of all kinds, Shafts, Dies, Hammerheads, Crossheads for Locomotives, etc.

12,000 Crank Shafts of this steel now running proved superior to wrought iron.

CRANK SHAFTS, CROSSHEADS and GEARING, specialties.

Machinery.

GOLD AND SILVER

Grinding and Amalgamating MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

SPERRY'S

Wrought-Iron Frame

FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc., Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,250.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

10,204—PISTON PACKING—S. A. Youse, Sutter Creek, Cal. July 10, 1879.
10,234—DIRECT ACTING ENGINE AND DRILLING APPARATUS—H. Richman and U. K. Arnold, S. F. July 14, 1879.

German.
6,064—PRODUCING A NEW EXPLOSIVE—E. Judson, S. F. English Patents.

Which have passed the Great Seal:
299—APPARATUS FOR PRODUCING LIGHT BY ELECTRICITY—E. J. Molera and J. C. Cebrían, S. F.
562—FASTENING FOR BOOTS—Eli Rees, Merced, Cal.

Notre.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

HUB-MORTISING MACHINE ATTACHMENT.—Plummer H. Parsons, Sacramento, Cal. Dated Aug. 19th, 1879. This invention relates to a novel attachment for that class of machines which are used for forming the mortises in wheel-hubs, into which the spokes are driven. These mortises are formed by suitable cutters, while the hub is supported in a horizontal position upon an apparatus which is provided with a spacing-disk to suit the number of spokes which the wheel is to have. After these mortises have been cut, it is customary to bevel-off the sides of each mortise with a chisel by hand to receive the shoulders of each spoke, which consumes much time and is not accurate. This device consists in the employment of a rotary cutter provided with an adjusting device, so that each mortise can have its beveled edges formed of exactly the same depth as rapidly as the hub can be turned upon its support. Full information of this attachment may be had on application to Messrs. Waterhouse & Lester, Nos. 29 and 31 Fremont street, San Francisco.

SPOKE-TENON AUGER.—Robert W. Eaton, Watsonville, Cal. Dated Aug. 19th, 1879. This device relates to certain improvements in turning augers, and it consists in a novel construction of the cutter-head, and in a means for adjusting and making it center with the mandrel. By this construction the inventor is enabled to maintain any tenon in the center of the mandrel while being cut, so that when the mandrel is turned, its axis will correspond with that of the tenon.

THE CHANNEL TUNNEL.—It appears that the boring that is making at Sangette, in France, is not the beginning of the shaft from which the tunnel is to be bored, but is merely an experimental bore-hole, some five or six hundred yards above the village and about 100 yards from the shore, so that it is small wonder that for three months the work has been suspended, because of the too rapid infiltration of water, while a new pump of double the capacity of the present one is building, that is, one which can raise about 675 gallons a minute. The shaft for the tunnel when it is begun is to be sunk in the village itself, and will be sunk to such a depth as the experiments now making shall show to be necessary. The experimental shaft, which is at present only 123 feet deep, is to be sunk to a depth of 260 feet, the diameter of the bore being 11 feet.

LOCOMOTIVES FOR TOWING.—An experiment has recently been tried with success in France in using locomotives for towing in canals. A railway is laid down on the tow path about three feet from the side of the canal, and on this run small locomotives of four or more tons, according to the weight to be pulled. One man suffices to manage the locomotive. The cable used is about 180 feet long. In one experiment the locomotive weighed four and a half tons, including water and coal; the transported weight was 463 tons, excluding the weight of the vessel's iron hull. The actual velocity reached 2.5 miles an hour, which, on deducting delays (from crossing other vessels, passing through two bridges, etc.), was reduced to an average of two miles per hour. The towing of an empty vessel on the return journey attained a speed of six miles per hour; but so high a speed would injure the banks. It is estimated that three miles an hour should not be exceeded, and this would, in the circumstances, be reduced to 2.5. The mean speed of a horse on the towing path is only about one mile per hour, and the advantages of the other plan were fully demonstrated.

EYE PHOTOGRAPHY.—At the London Photographic Society, on May 13th, Mr. W. G. Bird read a paper on the "Photographic Vision," showing from researches made by Kuhne and Boll, that a visual purple pigment exists in the eye, and that a theory is based upon this fact of a result similar to that which takes place in photography. A fixation takes place of an image in the eye by physical changes in certain minute rods and cones found in some membranes of the retina. The experiments appear to confirm the old theory that the eye of a deceased person or animal retains the last visual impression made upon it.

EVERY new subscriber who does not receive the paper, and every old subscriber not credited on the label, within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect ourselves and subscribers against the acts and mistakes of others.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favoring. We intend to send none but worthy men.
J. L. TRAPP—San Francisco.

FRESH attractions are constantly added to Woodward's Gardens, among which are Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

HOW TO STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 416 Market St., second floor, S. F.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Gover Mining and Milling Company.

Principal place of business, San Francisco, California. Location of works, Amador county, near Drytown, California. Notice is hereby given that a meeting of the Board of Trustees, held on Wednesday, the 6th day of August, 1879, an assessment (No. 39) of Fifty Cents per share was levied on the capital stock of the corporation, payable immediately in gold coin or legal currency of the United States, to the Secretary, at the office of the company, Room 8, No. 402 Front street, San Francisco, California. Any stock upon which said assessment shall remain unpaid on Tuesday, the 3rd day of September, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 6th day of October, 1879, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Trustees, W. J. WILLSON, Secretary. Office, Room 8, No. 402 Front street, San Francisco, Cal.

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnages and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

CAST AND FORGED

STEEL SHOES and DIES,

CAMS AND TAPPETS,

Blake and other Ore Crushing Plates, Etc., for Quartz Mills. Also

Steel Cranks and Castings

Of every description. For Circulars and prices apply to

STEAM ENGINES, BOILERS, STAMP MILLS, FRUE VANNERS
(and Machinery) for Systematic Mining, Milling, Smelting and Concentration of Ores.
No. 145 Fulton St., CHICAGO, ILL.

MINERAL LUBRICATING OILS.

Both Dark and Light in Color, and Gravities to Suit all Classes of Machinery.

For use in all Saw Mills, Flouring Mills, Quartz Mills, Foundries and Machine Shops, and Railroads.

Natural Dark West Virginia Lubricating Oils,
FROM 19 DEG. TO 23 DEG. GRAVITY.

LIGHT PARAFFINE LUBRICATING OILS FROM 24 DEG. TO 28 DEG. GRAVITY.
CYLINDER OILS for use in all Cylinders.

A Full Stock of LARD OIL, SPERM OIL and other Lubricating Oils constantly on hand. Also

High Fire Test Water White Illuminating Oils,
FOR USE WHERE ABSOLUTE SAFETY IS REQUIRED.

Oil House of F. B. Taylor & Co.,

120 and 122 Front Street, - - - San Francisco.

RUSSELL'S AMALGAMATOR.

Patented June 25th, 1878.

SAVE YOUR GOLD
And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridges Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

This entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated. With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

Mining Machinery Depot,

PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

A. S. HALLIDIE.

Office, No. 6 California Street, SAN FRANCISCO.

SAN FRANCISCO, SATURDAY, SEPTEMBER 6, 1879.

VOLUME XXXIX
Number 10.

Sandholdt's Tap and Faucet.

We illustrate herewith an improved tap and faucet, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by Samuel Sandholdt, of Centerville, Alameda county. Many attempts have been made to substitute a permanent tap for the small spruce plugs which are usually employed to stop the faucet hole when a barrel is refilled with beer, and for this purpose, hollow screw plugs have been fitted into a screw bushing, those plugs having valves, and being operated by the action of screwing into the faucet. The holes in these plugs being necessarily small are often stopped by sediment or pieces of hop leaves, and as they cannot be removed, it is impossible to clean them perfectly, while the screw bushing will in time become loose and leak. Mr. Sandholdt's device is designated to overcome these obstacles by certain details of construction which the engraving will explain.

A, represents the head of the barrel or cask, into which the hollow internally and externally threaded sleeve, B, is screwed. An internally and externally threaded bushing, C, corresponding in length to the sleeve is screwed into it. This bushing or thimble is countersunk at each end, as shown, so that a tight joint is formed. The outer edge of the bushing, C, is provided with a flange or shoulder having a washer, so that when the bushing is screwed into the sleeve, B, this shoulder comes against the seat formed in said sleeve, and a tight joint is thus made. In this flange or shoulder are cut notches or slots by means of which a wrench may be applied so as to remove it from the sleeve when necessary.

Into this bushing, C, fits a plug or tap, D, having screw threads formed on it. At each end of this plug is a square head, b, for screwing it in or out, and on its inner end is a flange or shoulder, with a washer, and when the plug is screwed into place in the bushing, this washer and shoulder fit close into the countersunk portion of the sleeve on the inner side, thus forming a tight joint.

The faucet, E, has threads formed on it to correspond with those on the interior of the bushing, C, and at its end is a recess formed of suitable size and shape to fit over the square head, b, of the tap. On the faucet, E, is screwed a nut and washer, G, which may be screwed down the faucet and fit against the countersunk portion of the bushing to make a tight joint.

The sleeve is attached to the barrel by screwing it in a little. The bushing, C, is taken out of the sleeve, and the plug is screwed into this bushing until the flange and washer fit snug into the countersunk inner end of said bushing. The bushing is then screwed back into the sleeve by means of the notches on its edge, until the shoulder fits into the seat on the sleeve, the flanged end of the plug in said bushing being on the inside. The band is then tight and the contents cannot escape.

When it is desired to draw any liquor from the barrel, the faucet is placed in a position so that the recess on its end will fit over the outer square head of the tap. The faucet is then screwed in a short distance, when the nut and washer on said faucet are screwed down so as to fit tight against the outer countersunk end of the bushing, making a tight joint at that place. The faucet is then screwed further into the bushing, gradually unscrewing the tap as it enters, until the faucet takes the place of the tap and the tap falls into the barrel.

An opening is formed lengthwise in the faucet, communicating with the recess, so that as soon as the tap falls into the barrel the liquor may be drawn off through the faucet. The valve, H, regulates the flow. When the barrel is empty the tap may be removed through the bung-hole, or the bushing may be removed and the tap taken out through the sleeve into which said bushing screws.

In this way a tap and faucet is provided which has no springs to get out of order and which is simple in construction. No injurious pounding is necessary to insert it in the barrel, and any one may tap a barrel of beer without danger of any loss of contents by its spurting out just as the faucet is being inserted. The

joints are kept perfectly tight by the shoulders or flanges with washers on the inner end of the tap, and by the nut and washer on the faucet, so that no leakage can occur by the insertion of the faucet and displacement of tap or plug.

Electricity as an Illuminator.

This electric light as an illuminator, its cost when compared with that of gas, and the most economical mechanical means of generating it, are questions of sufficient importance to attract the attention of the scientific world. In view of the careful estimates made both in Europe and America it is doubtless proper to say that the question of cost is gradually nearing its final settlement. From experiments lately made in London for illuminating the Thames embankment and the Holborn viaduct, we learn from *Engineering* that a careful estimate of the expense has proved that the cost was the same as that of gas of equal illuminating power, without counting the interest on the expense of the plant of machinery and steam power, and their distribution. When this was added the cost of this electric light was found to be more than double that of gas. It appears that the machinery was

running at 60, as stated. It runs with 90 pounds pressure, cutting off automatically, and making 280 revolutions per minute, from cylinders 9 by 16 inches. The proportion of the pulleys showed that the light generating electro-magnetic machines made 1,250 revolutions per minute. This makes the consumption of coal $3\frac{1}{4}$ tons per week, which, at \$3.50 per ton, is \$12.25 for the cost of fuel per week. Two attendants are required, one to take care of the boiler and engine, and one to watch the 14 machines and lights; the pay of the two men is \$33 per week. The consumption of carbons in the candles amounts to about 12 cents per light a night, which, for 14 lamps during 7 nights, is \$11.76. To this, which is all the direct expense, should be added the capital invested in machinery, which with wear and tear will be about 10%. The cost of the 14 magneto-electric machines is \$400 each or \$5,600; engine and boiler, \$3,800; total, \$9,400 or \$940 per year, a saving over gas of about 80%, quite a large margin for accidents.

At the Mechanics' fair pavilion in this city, there is used at present a No. 7 Brush generator, supplying 16 automatic electric lamps, only 10 of which are used to illuminate the center nave of the building, which is 100 feet clear span by 441 feet long. The lamps are of 2,000 candle-power each, requiring a horse-power of $13\frac{1}{4}$ for the 16 lamps, which may be increased to 20 lamps.

About 1,000 five-foot gas burners are required

SANDHOLDT'S PATENT TAP AND FAUCET.

very imperfect, the electric carbon lamps or candles of Jablockhoff were very defective, and that there was a most wasteful diffusion and obscuration of the electric light. It was the same in the Kensington Museum, which afterward was lighted with eight of Werderman's lamps. The electric generator employed was one of the early and obsolete Gramme machines, driven by a gas engine of $4\frac{1}{2}$ horse-power, and consuming 280 cubic feet of gas per hour. If we reckon the gas at only \$2 per 1,000 cubic feet, it amounts to 56 cents per hour, while $4\frac{1}{2}$ horse-power obtained from coal would require 20 pounds of coal per hour at the utmost, which, at \$3 per ton, is three cents per hour, so that the gas costs almost 20 times as much as coal would have cost. The eight electric lamps took the place of 30 argand burners, consuming together 140 cubic feet of gas per hour; so that the electric lamps required for their feeding twice the amount of gas sufficient for the gas burners. The English papers, however, are confident that better results would have been obtained if better machinery had been employed, and we think so too.

Madison Square garden, in the city of New York, as is stated in an exchange, is now lighted up by 14 electric lamps, furnished with their required electric currents by 14 Fuller magneto-electric machines, driven by steam power, and furnishes the following details: The large building is 400 by 200 feet in size, and required 4,000 gas jets, the gas bill per night being \$60. The electric illumination now used in lieu thereof was offered at one-half the cost of the gas. The steam engine driving the 14 magneto-electric machines was stated to exert 60 horse-power: The coal consumed in a Babcock & Wilcox water tube boiler was half a ton per night of five hours, or nearly $3\frac{1}{4}$ pounds per horse-power per hour. The engine is a Porter Allen engine of 57 rated horse-power, but run-

ning at 60, as stated. It runs with 90 pounds pressure, cutting off automatically, and making 280 revolutions per minute, from cylinders 9 by 16 inches. The proportion of the pulleys showed that the light generating electro-magnetic machines made 1,250 revolutions per minute. This makes the consumption of coal $3\frac{1}{4}$ tons per week, which, at \$3.50 per ton, is \$12.25 for the cost of fuel per week. Two attendants are required, one to take care of the boiler and engine, and one to watch the 14 machines and lights; the pay of the two men is \$33 per week. The consumption of carbons in the candles amounts to about 12 cents per light a night, which, for 14 lamps during 7 nights, is \$11.76. To this, which is all the direct expense, should be added the capital invested in machinery, which with wear and tear will be about 10%. The cost of the 14 magneto-electric machines is \$400 each or \$5,600; engine and boiler, \$3,800; total, \$9,400 or \$940 per year, a saving over gas of about 80%, quite a large margin for accidents.

SAHARA RAILWAY.—The project of constructing a railroad across the great desert of Sahara has assumed the phase of a commission, which held its first meeting in Paris last July, and appointed four sub-commissioners, who will devote themselves to documentary data, technical studies, explorations, and international bearings.

Lunar Influence.

In our issue of Aug. 23d, we took occasion to allude to the popular fallacies concerning the influence of the moon upon terrestrial meteorology.

The article was suggested by the letter of Prof. J. P. Nichol, the eminent Glasgow astronomer to the *Boston Journal of Chemistry*. Since that article several communications have been sent the latter journal from persons who suggest that the attraction of the moon upon the earth's atmosphere may produce tides like those of the ocean, and that these may have a decided influence upon the weather. A correspondent in Florida writes as follows:

"While conceding the fact that the superstitious belief of the influence of the moon in mundane affairs, so prevalent throughout the world, is not only unscientific, but quite ridiculous, shall we ignore the influences of attraction which she exerts upon the waters of this world, heaping them in a tidal wave? And might we not suppose that the same influence would produce a similar phenomenon upon the atmosphere, causing a 'tidal wave' to follow her in her apparent daily revolution around the earth? These waves, like the tides, would vary each day according to the position of this moon in her orbit; and of course whatever influence they might have upon the atmosphere, that influence would be greater at the new and full moon, when acting in conjunction with the sun, than at intervening times. I have noticed for several years past that the frosts of spring and fall in the Northern States usually occur at or near the time of new or full moon, and I have attributed the cause indirectly to the influence of the moon upon the atmosphere by attraction."

A friend in Alabama writes in a similar strain, but more at length, and remarks in conclusion: "That there is a certain coincidence between changes in the weather and changes in the moon is a fact which my own observations, extending over a period of more than 25 years, render it impossible for me to doubt. These observations have been conducted, it is true, only with the means provided by nature, including a very thin skin, and a nervous system which detects an 'east wind' before it has affected the weather-cock."

We have no wish to argue with those who insist that the moon does exert an influence upon the earth's atmosphere. The facts are that the variation in atmospheric pressure depending on the position of the moon is almost infinitesimal, and can be detected only by taking the mean of the most careful observations continued through long periods of time. At Singapore, in latitude $1^{\circ} 18'$, according to Prof. Loomis, the pressure when the moon is on the meridian is .0057 of an inch greater than when she is six hours from the meridian. At St. Helena, latitude $15^{\circ} 55'$, the difference is only .004 of an inch, and in higher latitudes it is still less. These results indicate a "tide" so slight as to be utterly insignificant in comparison with the atmospheric fluctuations due to other causes, and any influence it may have upon the weather is of course inappreciable. It can no more enter into our calculations or prognostications of the weather than the lunar heat, which, as we have said, is sufficient to raise the thermometer only one five thousandth of a degree.

From a careful scientific examination we are obliged to say that the same reasoning is applied to the moon as has been in the case of comets and other phenomena. Wars and pestilences have sometimes followed the appearance of comets and meteoric displays, which have been considered causes of the former, an ancient superstition not yet wholly eradicated.

DARIEN CANAL.—The scheme of De Lesseps, for cutting the Darien canal, seems to have been dropped for the present, the subscription books having been closed. The kindness of the French projectors in offering to dig this canal with American gold, and retain its control, has not been appreciated, and the lack of funds, combined with a plainly expressed American opinion, seems to have paralyzed any further advance in the matter, at least under the present auspices.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

El Dorado County Mines.

EDITORS PRESS:—The attention of capitalists willing to invest in mining speculations is now directed towards El Dorado county, and, at the present time, especially towards Greenwood. Much has latterly been written respecting the mining outlook in this locality, and it may not be out of place to carefully examine into and impartially report the condition and prospects of the several mines in the district. With your consent I will endeavor to do so, premising that I am an old miner and am not personally interested in any mines here.

It is well known that the neighborhood of Greenwood and the Spanish Dry Diggings has very largely helped to swell the gross returns from the northern California mines ever since the days of the earliest golden discoveries. With the exhaustion of the alluvial deposits, in the ravines, gulches and tributaries of the American river, the mining population has gradually decreased, till the few left in the old mining camps are generally those who still have faith in the discovery of profitable ore deposits in the quartz ledges and mineral seams in the hills, and who have labored on prospecting for inducements to encourage capital to carry out their enterprises. With varying success this has been partially accomplished. There is little doubt that had a moiety of the capital and scientific skill that has been expended on the Comstocks, El Dorado county, traversed as it is with mineral belts, would to-day have been as prosperous and celebrated as ever Virginia City was in its palmy days.

The first outlook that attracts the miner's attention on arriving here is the

Greenwood Seam Belt.

Which is distinctly traceable for a number of miles, and from which much of the wealth formerly obtained from the adjacent creeks and ravines doubtless had its origin. This belt is porphyritic and stratified, bearing northeast and south west (having the same course as the most prominent quartz ledges), varying in width from 400 to 600 feet; the walls are well defined—slate on one side, porphyry and gypsum on the other, the ground when opened presenting innumerable fine quartz seams, running in every direction, almost in cubes, but in depth these seams appear to be all converging to a common center. The ground, besides occasional rich pockets, contains an average distribution of free gold and rich sulphurets in considerable quantities.

The French Claim.

Located on the confines of the town site, is the most fully developed. It has been worked for many years and has produced upwards of \$2,000,000. It has been worked under the great disadvantage of poor dump facilities and too light a grade to carry off the debris. The tailings have been accumulated on the hillsides, at much extra labor and expense, and as much of the cement is washed out in its normal condition, in due time it will again be profitably worked, both for the gold and rich sulphurets therein contained. The last clean-up in this claim (last week), for a run of five days, returned 12½ pounds of pure gold, worth \$19 an ounce.

West of town along this belt are the Johnston & La Shantz, the Oakland, Union, Spanish and Bower mines. The two former of these are being opened, and will shortly be heard from. The Union and Spanish are at present lying idle, on account of some controversy as to title; and the

Bower Mine.

A more recent location, is being quietly, but methodically opened by an Eastern company, formed by Mr. Bower, the locator, and is worthy of special attention, as it will most probably be the cause of renewed activity along the entire belt. It is located where the belt is intersected by the American canyon, a deep gorge running from Greenwood to the American river, forming an outlet for dumping and reworking the tailings not afforded elsewhere, for which purpose the company have wisely located a claim of 3,000 feet of the canyon below. The area of the claim contains some 40 acres of the belt, part of which is a basin on Frazer's flat, the surface of which has heretofore been partially and imperfectly worked with great profit, but for want of fall had to be abandoned. The entire surface in this basin prospects gold more or less to every part. The company are running a tunnel from the side of the canyon to this basin, and are now in 450 feet, with a distance of 150 feet more to run, when they will raise a shaft some 87 feet to the surface and wash through the shaft and tunnel. The latter is run on a sluice grade of 14 inches in 12 feet, and when complete will contain a flume two feet wide, and drop into the canyon, the natural advantages of which will be aided by mechanical skill in a system of flumes, drops, etc.; and the accumulation of tailings from the summer's work, slackened by exposure to the elements, will be easily and economically worked in the winter, with the abundant supply of free water incident to the topography of the location during the rainy season, a system of undercurrents and other

appliances being used to concentrate the sulphurets, and thus, by the combination of nature and art, thoroughly work, at comparatively trivial cost, the debris for all it is presumably worth. Certainly the Bower mine gives very flattering prospects to the enterprising company, both for a speedy return of their outlay and a permanent and profitable mine.

As I am exceeding the limits of a letter, I will postpone my remarks on other mines for the future.

Greenwood, Aug. 26th, 1879.

Tybo, Belmont and Austin, Nevada.

EDITORS PRESS:—From Eureka south, away for 90 miles along extended valleys, between towering mountain ranges, skirting rolling, desolate hills, through dry, worthless sage brush regions, with but three green, grassy or even weedy spots an acre in size the whole distance, and the traveler turns square to the right, straight into the lofty range over a mile up a sharp, narrow, rocky defile to a mining town called Tybo. It is a crowded line of buildings of odd styles of architecture along a single street, or possibly a second in a place or two, so pressed for space is the whole between precipitous, craggy mountains, rising over 1,000 feet high, yet so ruggedly grand we never tire in looking at them. Here an active mill and successful mine gives employment for a population of some 500 people, a good proportion being families. The enterprise is called the Tybo Con. mining company—President, Mr. English; Superintendent, Mr. Hawkins; Foreman, Mr. Nowell. We went through the mine and everything appeared well, prosperous and sure for a score or two of years to come. The vein averages four and one-half feet thick, clearly defined by walls dipping to the north at an angle of 60°, very uniform in richness, mined 1,000 feet deep, and being stopped out near 900 feet in length. The company has smelted all its ore for some seven years past; but five months since they effected a change to that of dry crushing and find it a decided success.

Other claims are also being opened in the immediate vicinity with excellent prospects; the one appearing to us the best being that of the Gilmore Bros. Their vein is clearly marked, rich, and rapidly widening, though opened as yet to a very limited depth. On our way we passed two important mining points, not sufficiently developed, however, to justify our spending a day to visit them. The first was called Moray, four miles off the road to the west at the foot of a mountain of the same name, the highest, grandest, most rugged in the region. The other is Hot Creek, where the materials were just arriving for a new 10-stamp mill, designed to develop a number of mines in the vicinity till now lying idle.

We found at Tybo, as usual, many old friends of the PRESS, and took many new names of those who desired to receive it. From here 35 miles west, a little north, took us over two high ranges and across a wide valley to Belmont. This is an old and once famous mining locality. It may again become all it ever was or much more. Its principal claims are the Belmont, Highbridge, Monitor and El Dorado, while others are waiting development. The first alone, just at this time, is being worked, the others all being, for causes known to themselves or their owners, closed; the Highbridge stopping only the day before our arrival.

We were told as to the Belmont that strict orders have been received to admit no visitors into the mine, yet as we went through the mill, examined the piles of vein rock, and made various inquiries, our impressions were decidedly favorable as to the permanence and real value of this mine, and also to others near it, if only the owners could harmonize their views, and go vigorously to work in sinking deeper their shafts, and developing more fully the veins. Still, if all visitors are excluded it is not well for the agent of the MINING AND SCIENTIFIC PRESS to give a very decided opinion as to their claims. Still, we do expect them again to become of great value in their yield of the precious metals.

The town is the county seat of Nye county, and is really a pleasant place, with fine court house, public school, two church buildings, and six really ornamental, irrigated, green grassy dooryards, a real beauty in the desolations around. From Belmont over the Range west, then 70 miles north along Smoky valley, then again over a range west, and we came to one of the early, regularly laid out, prosperous, and respectably-looking mining cities of the State named Austin. Its one large milling company called the Manhattan, known the world over for its successful operations, appears to be carrying steadily forward its enterprise, developing its own numerous mines, and reducing all the ore which other miners in the regions bring it. They have an excellent mill, sparing no pains to secure the best of machinery, and do their work well. They have the admirable air compressor advertised in the PRESS on the last page, from the mining depot of Parke & Lacy, the very one exhibited at the Centennial. The Eureka Con., at Eureka, also has one of the same kind and all speak well of them.

The Austin mines consist of innumerable small veins of excellent pay ore running nearly parallel, from one inch in thickness up to, in

rare cases, two and one-half feet. Thus the labor of getting out the rock is often very costly. Yet when the rock is out, it has often yielded hundreds of dollars to the ton, up even to \$2,000 or \$3,000 or more. The mines may last for ages and not be exhausted.

The town has many houses, well built, and ornamented with fine trees and irrigated yards in true civilized manner. One street might well be called Locust, so well it is shaded by this pleasant exotic. Its court house, Methodist, Roman and Episcopal churches are large, fine brick buildings, each with good hell and completely furnished. Besides these there are also many private buildings and business houses of brick, as well as many well-framed and neatly painted dwellings. The rougher peculiarities of a mining town are steadily disappearing from Austin, and the features of true civilization are taking their place. A good railroad, now projected from Battle Mountain to this place, would greatly help to render it a place desirable for permanent residence and would add much to its business. Its view to the west is an extensive and most varied scene across Reese River valley to hills, mountains and ranges commencing beyond 20, 40 and 60 miles away. On the east, the immediate bills raise their summits to the lower clouds, and form a grand background to the city. Well may Austin be admired for its improved and natural features.

S. V. B.

Mines in Southern Utah.

Dr. J. S. Newberry, in the Salt Lake Tribune, gives the result of his observations in southern Utah. He finds very interesting features in that Territory. He pronounces the Tintic district the most interesting of all, and one that promises to be permanently productive.

The most important mines yet opened there are located on a great north and south vein, which have been traced and worked for a length of more than a mile. The mines situated on this are: The Eureka and Sunbeam on the north; the Crismon Mammoth, in the middle, and the Copperopolis on the south. This is a true fissure vein, cut through massive limestones across their bedding, and although exhibiting considerable variations in dimension and composition, gives every indication of being continuous and productive to a great depth. At the south end of the Crismon Mammoth property the croppings of the vein are nearly 200 feet wide, but it is here like the Comstock, divided by several horses of the country rock. Below it is more concentrated and shows what may be regarded as a normal thickness of from 40 to 60 feet. In its northern and southern extensions this vein is not as large, and of somewhat different composition, being relatively richer in silver on the Eureka, in copper on the Copperopolis. It everywhere carries copper, lead, silver and gold; the gold being most abundant, so far as we can judge from present developments, in the Crismon Mammoth, from which a considerable quantity of gold ore of extraordinary richness has been taken, assays being reported as high as \$80,000 to the ton, and specimens taken from the mine by him, assayed \$40,000 to the ton. Dr. Newberry is careful to say that the quantity of this rich ore is small.

The ore of the latter mine, however, contains about twice as much gold, in value, as silver; but the mine also holds great quantities of copper ore that will run from 12% to 20%. At present the chief product of the mine is gold, but little of the silver being utilized, and the copper entirely neglected. The ore is what is termed in this country "rebellious," and requires for its proper treatment a somewhat complicated metallurgical process.

The Doctor finds defects in the processes of extracting the precious metals, and says that the true interest of the district require the introduction of other methods of treatment. In the Sunbeam the unoxidized ore is mainly gray copper (tetrahedrite) with considerable iron pyrites, carrying much more silver than gold. This is treated, and it is said successfully, in combination with other ores, by the leaching process at the Ely mill, and there are several other mills in the vicinity in which the Tintic ores are worked by the ordinary amalgamating process.

Probably the best results would be obtained by matting the ores, as fuel is cheaper here than almost anywhere else in the Territory, wood costing but \$2 per cord, and the composition of many of the ores being especially adapted to this process.

Another mineral belt in Tintic runs in an easterly direction from Silver City. It includes the Julian Lane mine, remarkable for the bismuth silver it contains, and some other interesting mines in its vicinity, with an extension eastward of silver-lead ores, apparently along the line of contact between a broad dike of rhyolite "porphyry" and a ledge of quartzite. The mines appear at great disadvantage, having been irregularly worked.

The Eureka Hill has lately yielded considerable high-grade ore.

The Copperopolis is now closed, the low price of copper, its chief product, making it unprofitable working. Better methods of working must be adopted.

The Frisco district attracts Dr. Newberry's attention, and he pronounces the Horn Silver mine as the richest mine known in the world,

that is, the mine in which the largest amount of ore, and that of the greatest pecuniary value, can be demonstrated to exist. The mine is located on a true vein, which occupies the line of contact between trachyte on the east and limestone on the west. The limestone wall is remarkably regular and well-defined, both on the property of the Horn Silver company and the extensions north and south. The hanging wall has, however, been generally removed along the outcrop, and replaced by wash from the hills. The mine recently caved in and rendered some portion of the ore body inaccessible. The extent, laterally and vertically, of the Horn Silver ore body, has not yet been ascertained. It has been penetrated by the subterranean workings about 300 feet laterally and vertically. Careful measurements made by Mr. Hooker, part of which were tested and confirmed by Prof. N., show that the ore body extends at least 300 feet along the horizon, and to the depth of 300 feet from the discovery, with an average thickness of not far from 50 feet. This would give about half a million tons of ore, independent of what may lie below the lowest workings, or north and south of explorations yet made.

Working results indicate that \$50 per ton is about the proper assay. If we accept this and also the fact that half a million tons of ore are now at hand, we must assign a gross value of something like \$25,000,000 to the ore in sight. The expense of turning this into money would not exceed \$25 per ton, leaving a net profit of about \$12,000,000. About 40% of lead would be the average tenor of the ore, and 200,000 tons of lead would be produced valued at Frisco at \$25 per ton, making \$5,000,000.

So far as yet penetrated the ore of the mine is mostly soft sulphate of lead, with some portions, which are harder, of sulphate of baryta. Scattered through the vein are small masses of born silver, from which the mine takes its name, and in the harder portions may be seen streaks and lumps of ruby silver, usually coated with chloride, the result of decomposition.

The Carbonate mine two miles north of Frisco is a true fissure vein from 12 to 15 feet wide in walls of trachyte. In general features it closely resembles the famous Bassick mine of Rosita, Colorado, except that in the latter the ore which cements the pebbles consists of tellurides of gold and silver, with the sulphides of copper, galena, zinc and iron, and is much richer.

The Cave mine situated in the Lincoln district 22 miles east of Frisco, is situated in a limestone mountain, and the ore fills galleries and chambers dissolved out of the limestone, precisely as in the Little Cottonwood district, and at Eureka, Nevada. But the ore seems to be more continuous than in either of the localities cited. The mine takes its name from caverns which were never filled with ore, and now present the appearance of ordinary caves in limestone rock. The ore of the Cave mine consists mainly of soft hydrated oxide of iron (limonite), containing on an average about \$30 to the ton in silver and gold. It is the best flux for the lead ores of this region known. Silver Reef was not visited by Dr. Newberry owing to excessive heat and dust, but he considers the reports of the district as very exhaustive.

CAUSES OF INJURY TO CABLES.—The teredo has been very destructive in its attacks upon the gutta-percha coating of sub-marine cables. Sharp-toothed fishes have often interrupted the communication between Cayenne and Para. Turtles have attacked the wire from Key West to Havana. A whale broke the cable in the Persian gulf, and lost its life by getting entangled in the wire. Lightning has destroyed one or two of the Mediterranean cables. In some places sub-marine currents have worn out the cables by friction against the rocks; in others they have broken by their own weight in spanning ocean valleys. The attacks of insects have been partially overcome by mixing poisonous ingredients with the gutta-percha.

NEVADA COUNTY BULLION.—The following mines of Nevada county, California, have made reports of their bullion yield for the month of July, as published herewith: Deadwood (quartz), \$6,100; Idaho (quartz), \$29,300; Milton (quartz), \$50,500; Murchie (quartz), \$5,000 North Bloomfield (quartz), \$28,900; Pittsburg (quartz), \$7,900. This is only about one-half of the bullion product for this section for the month of July. Some 20 or 30 different companies heretofore refuse to give information of their clean-ups. We know of three companies, not mentioned in the above list, who sent bullion to San Francisco during the month of July aggregating upwards of \$30,000.—*Transcript*.

GOLD IN SOUTH AMERICA.—In French Guiana gold digging commenced in 1856; and in the next six years about 13,120 ounces of gold were procured. A few years later the Dutch settlers began to work in the gold fields in their colony, and in the next two years ending 1867, gold to the value of £25,000 (\$125,000) was exported to Amsterdam. It is reported from Surinam and Cayenne that rich veins of gold have been found simultaneously in several parts of the auriferous area. One man, it is stated, in four weeks gathered upwards of 40 pounds weight of gold, with little labor, and similar instances of the abundance of the metal are numerous.

FOR the information of the New York Mining Record, we desire to say that from information the Emigrant silver mining company, of Lee district, Inyo county, Cal., has yielded \$90,000 in bullion and levied two assessments.

MECHANICAL

PROGRESS.

Improved Refrigerating Apparatus.

The export of fresh meat from this country to Europe has led to the invention of a number of processes for keeping the meat cool during the voyage. The most simple, and, so far, the most successful process, consists in making an air-tight chamber in the steamer, pumping air by means of a fan and special engine, through a series of pipes packed in ice. The air is cooled to about 35° Fahr., and is deprived of its moisture by condensation in passing the pipes, and the meat is preserved perfectly so long as the supply of ice holds out and the fan is kept in motion. An improved process recently announced dispenses with the use of ice and accomplishes equally good results, with only a moderate expenditure of power. The new method is founded on the simple fact of the heating and cooling of air when compressed and allowed to expand. A meat chamber of any convenient shape and size is fitted up, and near it is placed an air-compressor driven by steam power. The first result obtained is a heating of the compressed air, and to get rid of this heat, a spray of cold water is let into the chamber containing the compressed air, at each stroke of the compressor. This lowers the temperature to that of the cold water, and by an ingenious system of fine grating, the moisture that saturates the compressed air is extracted. The air is passed through a series of finely perforated discs, on which a large proportion of the water is caught and allowed to pass away through suitable valves.

Within the meat chamber are arranged a series of pipes hung up in zigzag form (probably straight pipes joint by return-bends), and the compressed air is allowed to pass through these, still farther chilling it and removing by condensation the remaining moisture. It then passes to the cylinder of an engine and is there allowed to expand in driving the engines. The exhaust air is then taken by pipes into the meat chamber, and there allowed to expand to atmospheric pressure. The engine is also coupled to the steam engine that drives the compressors, and thus the air in expanding performs a part of the visible work of compressing. By this ingenious process the air is cooled three times and enters the chamber, not only dry, but very cold. There is less waste of power by this process, and a far lower degree of cold and a freedom from dependence on ice. By taking the air for compression from the chill-room, a still lower temperature may be obtained, and by joining one apparatus to another, there is apparently no limit to the lowering of the temperature of the air. The practical limit is found in the freezing of the lubricants used in the engine that is driven by the compressed air. Oil is frozen solid and stops the engine, and in practice it is found that glycerine must be used, and here the process stops, for, if the chilling and recharging is carried farther, the glycerine must freeze, and the engine will be unable to move. The process has been kept in operation for three months without stopping, and has proved to be entirely practical and satisfactory, and will undoubtedly soon be tried on steamers making long voyages.

NEW CARPET-WEAVING MACHINE.—A syndicate of five English carpet firms, according to the Manchester (Eng.) *Guardian*, have purchased the patent rights for an ingenious carpet-weaving machine invented by an American, which enables them to produce a carpet—a velvet pile, in appearance and quality said to be a most luxurious article—at a very low cost, which they have named the Royal Axminster. The machinery is said to be very simple, occupying only half the space of the ordinary carpet looms. The worsted yarns forming the faces of the carpet are wound from ordinary bobbins on long bobbins the width of the carpet, the colors being arranged by a comb as the pattern requires. The ends are passed through metal tubes for delivery, and the bobbins in proper sequence are then fixed on an endless chain over the loom. As this chain revolves, metal clips seize each bobbin in turn, take it off the chain, and dip the ends of worsted among the warp threads of the carpet. Here they are at once firmly fixed, and a circular knife cuts off the worsted at a proper level. The bobbin is returned to the chain, and the succeeding one dealt with. Women are now working the looms successfully and earning good wages. The process is considered likely to revolutionize the trade in Axminster carpets.

HOP-PICKING MACHINE.—An ingenious labor-saving device for picking hops has recently been invented, the arrangement consisting chiefly of two rubber rollers, so constructed as to draw in the branch of the vine, while two steel rollers, having an opposition action, pick the hops from it. The machine is about the size of an ordinary wringer of clothes, is propelled by means of a treadle, and runs as easily as a light sewing-machine. From the picker the hops run into a sack, and this, when filled, is taken to a separator, which sorts the hops from all leaves or stems which may have gone into the sack, and from thence to the hop-house. The apparatus is estimated to pick as many as 20 to 30 boxes per day; and one separator is ample for a large number of the machines.

Large vs. Small Vehicle Wheels.

George A. Hubbard in a recent number of the *Scientific American* speaking of the relative amount of power required to move a given weight upon wheels of a certain size or diameter, and the amount required to move the same weight on wheels of double the size or diameter, says that the power required by the large wheel was represented by 22½ pounds, and that required by the small wheel, of only one-half the size, by 33½ pounds, or in round numbers, as two is to three. Mr. Prosser in the *Western Manufacturer*, questions the accuracy of these conclusions, and states that his experiments "show very conclusively that the power required is inversely as the diameter of the wheel, except the friction of the axle, which is a constant quantity in both, so far as starting is concerned. But even that becomes inversely as the diameter when equal distances are passed over by each wheel." Speaking on this particular subject, Sir Thomas Tredgold remarks on page 341, Vol. V., of *Engineering Facts*, that it seemed quite clear to him, that "as far as the friction of a wheel is concerned, if you double the radius of the wheel, you reduce the power necessary to move the carriage one-half," and expresses his astonishment that this truth, although repeatedly published in that country had been overlooked. To confirm his idea, he instituted a series of experiments, the result of which showed that the small wheel required 1.59 of its weight, and the larger wheel, which was double the diameter of the small one, only 1.113 of its weight, thus showing conclusively that when the constant frictional quantity represented by the load on the axle is deducted to an extent of say 5-100, as it should be from the smaller wheel, which requires two revolutions to equal one of the larger, it leaves the ratio of power required inversely proportional to the diameter of the wheels.

APPLICATION OF ELECTRICITY TO WAR.—It is now proposed that the officers undergoing a course of torpedo instruction on board the *Vernon*, at Portsmouth, shall also be required to familiarize themselves with the practical application of electricity to the art of war. The teaching element has not as yet been perfected, but proper instructors will, no doubt, be provided in course of time. Steam was got up in the *Dreadnought* on two occasions, and the first lessons in the production and management of the electric light were imparted. The turret ship is provided with a couple of lamps placed at each end of this flying deck, the current being generated by one of Wilde's electro-magnetic machines, the motive power for which is supplied by a strap from the forward ventilating engine. The illumination is produced by a couple of vertical carbon points, which are worked by hand. There is no subdivision of the current, so that only one light can be used at a time. Until lately, however, the after light could only be obtained by disconnecting this forward one and forming a new and separate connection with the commutator between decks. This method not only entailed great loss of time, but was attended with great difficulty. Now, however, an important improvement has been introduced, by means of which it is only necessary to shut off the forward connection, and the after light may be used at once. Some experiments have also been made with the Gramme machines on board the *Bloodhound* and a torpedo boat.

TRANSFORMATION OF SOUND INTO LIGHT.—M. Coulon, conservator of the Industrial Museum of Rouen, has discovered a new system for transforming sound into light, which phenomenon has been the subject of a lecture at the Salle des Capucines by M. Frank Gerald, with the Gower telephone. Two Geissler tubes are put in quick rotation on an axis. The Ruhmkorff coil of the first is worked by an ordinary interruptor and gives the deviation of a luminous cross. The interruptor of the second is replaced by a telephone. The figures presented by the second tube projects on the first one, which is colored by uranoxide glass and exhibits the most rapid changes according to the height of the notes delivered in the telephone trumpet. The sensibility of the changes are startling and most interesting. An exhaustive lecture by M. Coulon will be given at Rouen in a few days, and the apparatus exhibited at the Palais de l'Industrie.—*Iron*.

HEMP-SOFTENING MACHINE.—The Mohawk and Hudson Manufacturing Company, of Watford, Massachusetts, has recently built and shipped to the hemp region in Kentucky, a hemp softening machine, which is believed to be the largest and heaviest in the country. It has two fluted rolls. The lower one is 12 inches in diameter and 6 feet long. The upper one is 24 inches by 6 feet. The lower one is driven by gearing from the back shaft, and in turn it drives the upper. The shafts are 6 inches in diameter. The upper roll and shaft weighed about 8,500 lbs., and the complete machine about 15,000. Other hemp-softening machines have been built at these works, but none as large and heavy as this.

AMERICAN ENGINES.—Locomotives of American manufacture are rapidly conquering those of European make in economy and favor. They are much less in cost than English engines in South America and Russia, and are gaining in favor.

SCIENTIFIC

PROGRESS.

Negatives on Paper.

The success which has followed the practice of the gelatino-bromide process and the easy character of its manipulation have revived, says John Nicol, Ph. D., in the *British Journal of Photography*, the desire for a substitute for glass as a support for the sensitive film. The Rev. H. J. Palmer has already shown good work on a gelatino film, and several operators have been more or less successful with various substances; but we want something simpler and less troublesome before glass can be dispensed with. One of our successful northern amateurs is at present getting pretty good results on simple paper. The kind he at present prefers is known as letter-book paper—a variety extremely thin but tough, and with a perfectly smooth surface. A roll of this, slightly dampened, is laid on a perfectly level board a little narrower than itself, and the edges folded over and fastened with gum to keep it flat. The emulsion is poured on and spread with a glass rod in the ordinary manner. When dry it is cut into suitable sizes and exposed between plates of glass, as was the case with waxed paper. So far the results are promising, and I have little doubt that some such arrangement will ultimately be found in every way satisfactory for all outdoor work. It is probable that a previous coating of rubber in benzole, as suggested by me a number of years ago, might be an advantage by keeping the emulsion on the surface. Should simple paper be found to answer, as I have little doubt it will, some of our enterprising manufacturers will soon be sending it into the market in rolls similar to carbon tissue, as it may be made by the same apparatus and in exactly the same way by simply substituting the sensitive emulsion for the pigmented gelatine. In addition to the advantages of lightness and non-liability to break, there will be the further and, to many, great advantage of reduction in cost. The price of glass is altogether saved and the labor reduced to a minimum, a band of several yards being coated in the most perfect manner in a few minutes. I hope to return to the subject again as the experiments of my friend proceed, and trust that, meanwhile, other workers will turn their attention in this direction, as the greater number who put their hands and heads to the work the sooner will the desired end be accomplished.

APPLICATIONS OF STEAM ENGINE.—John Bourne, C.E., London, in his pamphlet entitled the "Steam Engine of the Future," says: "The application of the steam engine to the propulsion of carriages, omnibuses, and cabs, is now only hindered by its too heavy weight and too high cost. Asphalt pavements, which are objectionable for horses, afford for steam carriages a surface as eligible for easy traction as a railway, and without any countervailing fault. All wheeled vehicles, whether required to travel at a high or a low speed, will be propelled by steam instead of horses as soon as the steam engine is made efficiently light and sufficiently cheap to warrant the substitution. Life boats, instead of being open boats propelled by a number of men, should be decked boats propelled by a steam engine, and managed by only two men, one to steer the boat and the other to attend to the engines. Such boats should be propelled by a water jet which will always act, whatever may be the roughness of the sea, and whether the stern of the boat is in or out of the water. The use of the steam engine for irrigation in connection with the centrifugal pump is an application of which the sphere is limited only by the cost and the deficient portability of this apparatus. To render the class of small engines so much more portable, so much more simple, and so much less costly as to remove the existing impediments to their use, may certainly be accounted one of the most important problems of the present time.

CURIOSITIES OF EARTH.—At the city of Medina, in Italy, and about four miles around it, wherever the earth is dug when the workmen arrive at a distance of 63 feet, they come to a bed of chalk, which they bore with an auger, five feet deep. They then withdraw from the pit before the auger is removed, and upon its extraction the water bursts up through the aperture with great violence, and quickly fills the newly made well, which continues full and is affected neither by rains nor drouth. But what is the most remarkable in this operation is the layer of earth as we descend. At the depth of 14 feet are found the ruins of an ancient city, paved streets, houses, floors and different pieces of mason work. Under this is found a soft, oozy earth made up of vegetables, and 26 feet, large trees, with the walnut sticking to the stem, and the leaves and branches in a perfect state of preservation. At 28 feet deep a soft chalk is found, mixed with a vast quantity of shells, and this bed is 11 feet thick. Under this vegetables are found again.

ECONOMY OF ELECTRIC CARBONS.—M. Delanrier says that by guarding the poles of the electric circuit from air currents, an atmosphere of carbonic acid may be formed around them, which prevents useless waste and greatly diminishes the cost of lighting by electricity.

Lord Derby and the Arctic Expedition.

The projected Arctic expedition for the discovery of the North Pole will, in all probability, leave England in the spring of 1880. By the exertions of Commander Cheynes, a London Arctic Committee has been established at the head of 49 other committees throughout the country. Commander Cheynes is endeavoring to secure the patronage of Lord Derby and other eminent noblemen and scientific gentlemen, and a memorial to this effect will be presented by a special committee of ladies, as well as by the Central Committee. The various committees will be asked to enter upon the work of collecting subscriptions. The expedition will co-operate with those sent out by Sweden, America, Holland, Austria and Denmark.

The following letter has been sent by Lord Derby to Captain Cheyne, Commander of the new Arctic expedition: "23 St. James' square, S. W., Aug. 1st, 1879. Dear Sir: Having heard your scheme of a new Arctic expedition fully explained in conversation to-day, I have the pleasure of promising a contribution of £100 in aid of it, should you succeed, as I hope you may, in obtaining support to justify you in going on with it. I remain, faithfully yours, DERRBY." Captain Cheyne, R. N. Mr. Puleston, M. P., is Secretary of the expedition fund.—*Liverpool Weekly Courier*, Aug. 2d, 1879.

A RIVAL OF THE ELECTRICAL LIGHT.—An intensified gaslight, by some called the "albo-carbon light," is attracting considerable attention in England at present. Its special advantages are that it economizes the consumption and improves the quality of the gas, and involves no change in mains, meters or piping, or the general apparatus of gas service. It is also claimed by the patentees that albo-carbon causes no obstruction and leaves no residuum; and that the evaporation of the substance under heat is so thorough that vessels in which it is used may be replenished without any fear of accumulating deposits. A variety of interesting photometric tests were recently applied to this light at an exhibition in London; and one of the most pleasing effects produced was that of its hue, which was cheerful and sunny as well as intensely brilliant; and the shadows cast by objects within its range were of a subdued tone quite different from the intense darkness that contrasts so unpleasantly with the moonlight brightness of the electric light, which requires at present for its production elaborated machinery not needed in connection with albo-carbon. This substance, used as an adjunct to gaslight, imparts to the latter a warm, sustained and steady light, that does not, in spite of its strength, fatigue or discommodate the eyes. As employed as an auxiliary to common gas, the improved light consists of some properties of pure white carbon in the solid form of small cylinders, having much the appearance of sticks of pure white candy. The apparatus required to adapt the feeder and enricher to an ordinary gas-burner is so simple that it demands a management no more skillful than that needed to fill and trim a common table lamp.

ELECTRIC LIGHT TELEGRAPH.—Mr. F. Peppard, of Basking Ridge, U.S.A., while using a small vibrating electric light, conceived the idea of making and breaking the circuit by means of a finger-key or commutator, and of employing this intermittent light for flash-signaling. When the current is on, if the key be touched, at each depression it makes a corresponding flash in the light, which can be seen and read miles away—in fact as far as the light can be seen; in this way each letter of the alphabet can be flashed out, the flashes taking the place of the dots and dashes in the Morse system. For government or private use, a secret system could be used which could be read only by those holding the key to it. The advantage to the Admiralty of giving secret orders to officers who may be miles away, and which can only be understood by them, would be invaluable for war-vessels, forts, etc. The garrison of a fort could attach a light to a very small hallion, and send it up a few hundred feet, and flash out its dispatches, which could be seen and read as far as the light could be seen. The light used is of a vibrating kind, with an armature that will give instantaneous flashes, and the cost of an apparatus sufficient to produce a light which may be seen for many miles does not exceed \$100.

NEW PENDULUM EXPERIMENTS.—M. Dejean des Fourques has experimented with a pendulum, vibrating in a large arc and free to move in all azimuths. He finds that the plane of oscillation tends rapidly to assume a special direction, which is, according to his views, the horizontal projection of the earth's trajectory, or, in other words, the resultant of the two great movements towards the constellation Hercules and around the sun. The path traverses the meridian four times a day, and the hours of crossing vary with the position of the earth in the ecliptic. M. A. Corwin has witnessed the experiments and reported them to the French Academy. Although he hesitates to adopt Fourque's conclusions with regard to the cause of the movements, he thinks them so interesting and important that he recommends them to the careful study of physicists and geometers.—*Comptes Rendus*.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

ITEMS.—*Dispatch*, Aug. 30: The cam-shaft of the Governor mine, which was broken about a week ago, was fixed up and is now working order last night, and the mill is now crushing away as usual. At Plymouth the mining out-look was never better than at present. There are three mines in prospective operation and we hope to give you something more authentic soon.

INYO.

MONROE.—*Independent*, Aug. 30: South drift, 300 ft. point, run 16 ft; north drift, 300 ft. point, run 12 ft; south drift, 800 ft. point, run 17 ft; north crosscut, 1000 ft. point, run 18 ft; south drift, 1100 ft. point, run 12 ft. Total length of south drift, 300 ft. point, 172 ft. North drift, 300 ft. point, 80 ft; north drift, 800 ft. point, 144 ft. North crosscut, 1000 ft. point, 20 ft; south drift, 1100 ft. point, 144 ft. The face of the north drift, 300 ft. point, continued in ore, as at last report. At a distance of 18 ft in this drift ore came in at the top and at half the present length of drift the top, bottom and face was in ore. At a short distance from this point they cut through the ore in the top of drift and have since had it out about two-thirds up in the face, also in the bottom, with little variation. The south drift of this ore vein has been downward and into the hill, following the direction of the drift. The ore at the face of drift appears much stronger and is in better ground than at any previous time. Assays from the drift, made to-day, run as follows: No. 1, 70; lead, 130; 9 ounces silver; No. 2, 41; lead, 194; 40 ounces silver; No. 3, 37; lead, 155; 63 ounces silver.

LOS ANGELES.

ITEMS.—*Gazette*, Aug. 30: Some excitement exists in Shrewsbury canyon over the reported discovery of a rich gold ledge. Three quills of gold dust were mined at San Jacinto. The dust was of fine quality, being rated at \$18 an ounce. A gentleman who returned Monday from the vicinity of the San Gabriel canyon, reports having discovered a fine placer mine in a new location. He brought in about \$15 worth of coarse scale gold with him as a sample.

MONO.

STANDARD.—*News*, Aug. 31: The north drift, 355 level, is in 355 ft; the ledge is three and one-half ft wide, and looking very well. The stope on this ledge are looking particularly well, especially in the south end and where the ledge is about 10 ft wide of very rich ore. The winze on the 550 level has reached a depth of 115 ft; the ledge is four ft wide, of very good ore. The upraise is up 120 ft, showing a ledge 10 ft wide, of good milling ore. The west crosscut, 300 level, is in 68 ft. In the West Standard stope the ledge is about 10 ft wide and of fine ore. In the south drift, 550 level, the ledge is from 10 to 15 ft wide, of good ore. In the Glidea stope the ledge is about three and one-half ft wide, of fine milling ore.

TOOIA.—No. 3 vein, 520 level, is down 20 ft; becoming richer and the gold coarser. The southeast and northeast drifts of the Mono level depend about the same results.

VORTEX.—The ledge in the bottom is two ft wide, of fair milling ore; average assays during the week running from \$45 to \$45 per ton. Connection will soon be made with the west crosscut from the Osceola mine, and will cut the ledge at a depth of 200 ft from the surface.

SOUTH BELLEVUE.—Drifting on the ledge, 350 level, which is three ft wide, of solid, lumpy quartz and good milling ore. Drifts have started north and south from the bottom of winze No. 2. The ledge in both drifts is looking well; two and one-half ft wide of fine milling ore. West crosscut, 420 level, advanced nine ft during the week; total length, 45 ft—the face being in a favorable formation of quartz and clay, with every indication of soon striking the ledge.

THE WORK.—The main shaft has reached a depth of 335 ft in good working ground. The winze on the Warren vein, from the 320 level, is down 150 ft, and in very favorable quartz and clay. The east drift on the 320 level is in 120 ft. The winze on the Liberty vein, from the 220 level, is down 37 ft, and the ledge improves greatly as depth is attained.

SUMMIT.—The north drift, 200 level, is in 345 ft. This is in 220 ft. The ground here continues very hard. The north drift, 300 level, has been run since last report 38 ft; total length, 328 ft. The ledge is two and one-half ft wide and looks well. The south drift, same level, is in 311 ft; the ledge is three ft wide.

BULWER.—The south drift, 380 ft level, has been extended 10 ft. The ledge is two and one-half ft of good ore. The west crosscut from this drift is in 42 ft. The winze on the Ralston ledge has reached a depth of 47 ft; the ledge is two ft wide and looks well. The formation in the tunnel is still very hard.

MCCONTON.—This company are sinking a new shaft some distance north of the old works, which has reached a depth of 92 ft. The ledge at the bottom is about two ft wide of good milling ore. The west crosscut on the 500 level of the old works is in about 60 ft. The north drift, on the same level, is in 45 ft, and has developed a 20-inch ledge. The drift on the Bulwer ledge is now in 62 ft, showing a ledge two ft wide.

CHAMPION.—The winze on the 400 level has been sunk 30 ft, with a good body of ore the entire distance. The south crosscut on the 400 level has been extended 40 ft, with a ledge of quartz of a good paying quality.

ANDREA.—Work for the past week has been chiefly confined to the 200 and 300 drifts. The former drift is now in from station 17 ft, and the latter 47 ft. This drift shows a well-defined ledge of low-grade ore. Progress for the week, 32 ft.

RED CLOUD.—The north drift on the 250 level is showing some very fine quartz. The ledge improves in strength and as it is opened up.

SOUTH NOONAN.—A winze on the ledge has been started from the level in the north drift; the vein is three ft wide of a fair quality of ore.

BELVIER.—The shaft is down 235 ft in vein formation carrying considerable quartz.

STANFORD CON.—The shaft is down about 125 ft. The formation of the rock is changing to a decomposed quartz, with a mixture of clay. A winze will be erected this morning.

UNIVERSITY.—Everything about this mine has the appearance of speedy development. The shaft is now down about 95 ft, with a very favorable outlook. The timbers, boilers, etc., are now on the ground for the new hoisting works, and they will be set in place as soon as the balance of the machinery arrives, which is now on the road.

BOSTON CO.—In sinking the shaft a new ledge about 16 inches in width was discovered, consisting of a reddish colored quartz, which assays about \$40 per ton. The richest assay comes from the bottom.

TRUE BLUE.—This mine is working with a full force; all the work is being done on main tunnel, which is now in 135 ft. Some fine seams of quartz are being exposed. Face of tunnel is now in basalt rock, quite hard, but breaks well. Indications denote vein close at hand. The croppings show fine ore in this mine. Immense quantities of ore in sight.

NAPA.

ITEM.—*Register*, Aug. 16: J. H. Francis is taking good ore out of the tunnel he is running into a ledge on his ranch, considering the depth he is cutting the ledge from the top—30 ft. The ledge is well defined, and shows better ore as greater depth is reached, that already taken from it being rich enough to pay well for milling.

NEVADA.

CHAPMAN RANCH CLAIM.—*Transcript*, Aug. 27: Messrs. Skidings & Spence commenced work on a ledge at Chapman's ranch near this city last Christmas. They first

took out a crushing of five tons, then another of nine tons, and about two weeks ago one of 13 tons. The ore has averaged \$40 per ton. The shaft in which they were working shows a two-ft ledge, but made too much water to permit of operations without machinery, and during odd intervals they have been engaged in running a tunnel to tap the lead. This tunnel is now in about 100 ft, and has recently been showing some encouraging signs in the way of cap-rock. There is no doubt but they will reach the ledge through it. It is likely that this claim may develop into an extensive one.

THE DEADWOOD MINE.—The mill at the Deadwood mine is now engaged in crushing the second 100-ton lot of ore that has been produced this month. It is high-class rock. The average product of the mine pays from \$35 to \$45 per ton.

A FOREST SPRINGS MINE.—William Hearne, John Noia and B. Courant struck the Lone Tree and Sunny Side ledge near the Shamrock mine, at Forest Springs, on the 24th inst., and the result is sufficiently encouraging to repay them for many weeks of untiring labor in the face of difficulties. Commencing work over a month ago, a shaft 20 ft deep was sunk, when the water came in so fast they had to abandon it. A tunnel was then started, and it was through the latter they reached the ledge, which is found to be about three ft thick, and reasonably rich in free gold. The claim has formerly been worked to some extent, but profitably.

PLANET MINE.—The tunnel of the Planet mine is in 1,000 ft. From the end of it an incline has been run 100 ft, following the bedrock which is pitching into the hill. The gravel looks well, and contains considerable fine gold. The company are running for the center of the channel, and feel much encouraged with their prospect. The tunnel is one of the finest pieces of work of that character ever performed in Nevada country. From the inner end the mouth of it is plainly to be seen, so straight is the line.

SIERRA.

ITEMS.—*Transcript*, Aug. 30: At the Oriental mine they have commenced work underground. In upraise from fourth level are working two shifts. The ore is very good, with a large percentage of galena sulphurates. The Santa Anita claim is looking splendidly. The ledge has been developed to a depth of 250 ft by shaft and tunnel, and is eight ft thick at that point.

SIERRA BUTTE MINE.—*Reno Gazette*, Aug. 30: The old Sierra Butte mine is working with a good result, crushing about 100 tons of ore per day. It is owned by an English syndicate. The old blue gravel channel has been struck, and is rich in free gold. There are several ledges of ore prospecting free gold and carrying small quantities of silver and some copper stains.

TUOLUMNE.

ITEM.—*Independent*, Aug. 30: R. C. Davis & Co. have been engaged prospecting a quartz vein near the celebrated Riverside mine of late, with the most flattering results. They have sunk on the vein 50 ft, and at the bottom of the shaft it is five ft thick and well defined. Mr. Davis exhibits some of the ore taken from the shaft that has been assayed. By simple tests it is ascertained to yield \$800 per ton. The ore is very rich, and is estimated to yield one-half the amount it shows by the ordinary process of testing, considering the size of the lead and the advantages for working it, it will be in reality a bonanza, and well worth the time and cost of discovery. This mine is called the Continental, is situated on the south tributary of the Stanislaus river, and about three-quarters of a mile above the Riverside mine.

YUBA.

ITEM.—*Appeal*, Aug. 29: After a run of eight months the Nevada company cleaned up this week and brought to Marysville \$24,000 or upwards.

NEVADA.

WASHOE DISTRICT.

NORTH BONANZA AND FLOWERY.—*Cold Hill News*, Sept. 3: The flow of water into the bottom of the shaft is lessening very fast. Crosscuts are being run from both north and south drifts, 400 level, 100 ft each way from the shaft, but neither crosscut has yet cut the ledge, although that to the north is showing indications of being very near the vein. Crosscut No. 1, north, 300 level, is in quartz giving better assays. No. 2, where the best ore was found, has cut through some eight ft of porphyry and is again in open up the west section of unexplored ground lying in this portion of the mines. The north drift, 1950 level, from crosscut No. 1, is in 117 ft, and is encountering some ore. The north drift on the 2150 level leading to the Ophir is still being graded down. The ore vein crossed by the main north drift on this level is being followed south. The new pump-rod is being put in at the C & C shaft. It will extend from bottom to top and carry the double line of pumps up to the Sutter tunnel level.

SIERRA NEVADA.—The water is held just below the station on the 2200 level, where a common pump has been placed to lift the water up to the level. In a day or two a drift will be started east from the bottom of the east shaft, 2200 level, from which to sink a winze and run a drift to connect with the 2400 station of the incline.

GRUBB.—The north drift, 2200 level, is being pushed on at the rate of 6 ft per day, the face in vein matter showing streaks of clay and quartz. From the end of the main drift east a crosscut has been started in search of the Hardy vein. Low-grade ore is being encountered on the 2100 level in the drift north from the west crosscut and running along the Hardy vein; total length of the drift, 30 ft. The joint Mexican crosscut on the 2000 level is cutting a fine vein streaks of quartz, total length, 92 ft. The stope yield their usual 50 tons of good ore.

JUSTICE.—Fine quartz giving moderate assays and occasionally a bunch of good ore are encountered in crosscuts Nos. 1 and 3, 1550 level. In the lateral drifts north and south, along the west ore chamber, some nice quartz and bunches of good ore have been found.

HALE & NORCROSS.—The mine has been freed of water, and the debris is being removed from the dump of the incline. No water has come in from the Savage since Sunday. East drift, 2100 level, is in 46 ft, and in hard rock. A winze will be sunk to the 2200 level as soon as the requisite distance is gained.

EAST BONANZA.—An incline shaft has been started on the east line of the ledge and is now down 33 ft. The old tunnel is being cleaned out and a full force of men are now at work on the claim.

EXCHEQUER.—The total length of the north drift, 2400 level, is 566 ft. It has now reached the north line of the mine and has been given to the Bullion for continuation.

NABARUA.—Oodoo prospects in both drifts north and south.

GRUBB.—The formation encountered in the east crosscut, 1600 level, is promising ledge matter. Since last report guides have been put in the north compartment of the mine from the 1600 level to this level and the air pipes have been changed.

BROPHY.—The tunnel has reached the vein and is in quartz yielding low assays. A drift has been started and will develop a vein 20 ft in width recently passed through.

TRONAN.—The west drift from the third station is in quartz and porphyry, the former giving good assays. The drift has been enlarged and retimbered, and track and turn-table have been put in.

GOLDEN STANDARD.—The tunnel, which is to intersect the Healdstead shaft, is in ground of purely vein formation carrying streaks and bunches of quartz, intermixed with clay.

SAVANE.—The station on 2200 level is not yet free from water. The heat is intense.

UNION SHAFT.—The shaft is being driven toward the 2200 level of the Sierra Nevada. The rock is hard; total

depth, 60 ft below the 2000 level. The drift west on the 1600 level to connect with that coming from the Union side is in 100 ft and in good working ground.

MEXICAN.—The joint Ophir crosscut west, 2000 level, is in vein porphyry carrying streaks of quartz; total length, 92 ft. The joint Union winze from this level encounters considerable water, although the rock is somewhat softer; total depth, 42 ft. The joint Union crosscut west encounters vein matter carrying streaks of clay and quartz, its face 82 ft from the main north drift.

CON. VIRGINIA.—On the 2150 level the east crosscut is passing through favorable material carrying strings of quartz; total length, 175 ft.

CON. CON.—The drift east, 1000 level, is being extended toward the Union shaft on an average 4 ft per day; total length, 200 ft. The joint Mexican crosscut, 2000 level, is making three ft per day through vein matter carrying streaks of quartz and clay; total length, 82 ft. The joint Mexican winze from this level is cutting softer rock carrying considerable water; total depth, 42 ft.

LADY BRYAN.—The raise for the incline from the 750 level to the 600 level was started up to-day. The north drift, 750 level, is cutting more quartz, which looks well. The south drift on this level is in hard porphyry. The drift west from the south drift, 600 level, is encountering a promising formation of clay, porphyry and quartz which gives low assays. The east crosscut from the north drift is in porphyry containing streaks of quartz.

ALTA.—The north and south drifts on the 1750 level continue to penetrate quartz and quartzite, and nearly the whole bottom of the incline is being pushed on down through a similar formation.

BULWAT.—The double incline winze from the 2150 level is now 104 ft on the slope below that level. The bottom is in clay, porphyry and quartz of a promising nature. The Eschequer drift north, 2400 level, has reached the Bullion line and has been taken up and is being carried on to meet the winze when it reaches that level.

ARGENTA DISTRICT.

ITEMS.—*Tybo Sun*, Aug. 30: Considerable fine ore is being taken out of the Oliver Twist mine. The returns from the ore assayed shows gold \$41, and silver \$347, total \$388. The New Philadelphia company mine Bismarck is opening out well and has yielded a good lot of ore now on the dump.

BELMONT DISTRICT.

ITEMS.—*Courier*, Aug. 30: Drift running south from No. 3 raise has been advanced 15 ft through a vein of quartz 15 inches of which is good milling ore. Raise No. 4 has been advanced 15 ft without any material change. Raise from 200 south level was advanced 12 ft through a streak of high grade chloride ore. The stope south of this raise is looking fine and getting larger every day, this body of ore will extend up to the old incline level, which is the top of the vein 160 ft above the 200 shaft level.

GILA.—The south drift winze No. 2 was sunk 5 ft during the past week, and drift from bottom of winze run 8 ft. In the former there is a wide vein of good ore, a part of which is very rich, an assay made of the best to-day giving \$1,470.50 per ton. The stope are all looking well.

CHIMNEY CREEK DISTRICT.

ITEM.—*Eureka Sentinel*, Aug. 23: Reports say that several very rich strikes have been made in this district. The Henry Clay, a new discovery in that district, owned by Messrs. S. E. Palmer, Bish. Luther, and others, is said to be a rich claim. This district is situated between two high mountains, with wood, water and grass in abundance, easy of access, making it one of the most attractive and convenient in the county.

EUREKA DISTRICT.

PHOENIX.—*Sentinel*, Aug. 30: The Superintendent says, for the past two weeks we have been running a drift to the southeast on the 200 level, after having run some 80 ft under the old croppings on the surface where a large amount of ore was seen in early times. We yesterday started a crosscut to the northeast at right angles to the footwall, and after proceeding a few ft, cut into a body of ore, the ore being high grade, but so far some what mixed with bunches of lime. We have raised some six tons of good ore out of this place in the past 24 hours, assaying about \$120 per ton, and at least 40% lead.

PARADISE DISTRICT.

ARTHIUS CON.—*Paradise Reporter*, Aug. 30: An important strike was made in this mine yesterday. The first blast in the ledge-to-day showed ore of a very encouraging character, with green copper or mineral streaks running through it. There has been a large amount of work done in tunneling to strike this mine, but at last the efforts of the owners are crowned with success.

SILVER STATE DISTRICT.

ITEM.—*Silver State*, Aug. 23: Angus Morrison has a force of men at work on the Olompi mine, in Black canyon, in the Humboldt range, east of the Humboldt House. This ledge was located in 1861. It is about 20 ft wide and it crops out boldly for a long distance on the surface. Mr. Morrison is drifting on the banded wall of the ledge, and at a depth of 10 ft from the surface the ore assays from \$10 to \$50, principally gold, to the ton. Choice pieces of the ore assay over \$100 per ton.

ETHAN ALLEN.—*Silver State*, Sept. 2: T. F. Harlan, assayer at Paradise valley, who recently visited the Ethan Allen mine, on Willow creek, reports it one of the largest ledge ever discovered in the country. It is located on Willow creek, where there is plenty of fuel and water for reduction works, six or seven miles from the Ohio mine. The ledge crops out about 100 ft wide on the surface, and is prospected by a tunnel which has been run 30 ft into the ledge, showing ore all the way. The ore assays from \$30 to \$900 in silver per ton, the average being considerably over \$100.

TYBO DISTRICT.

ITEM.—*Tybo Sun*, Aug. 30: The Tybo Con. is yielding well, \$2,200 bullion shipped to-day, and three bars more ready to ship. Work is being prosecuted with vigor on the G. F. mine. The vein is now four ft wide, all of which is good milling ore. A windlass is being erected and a blacksmith shop built at the mine to facilitate work.

WILLOW CREEK DISTRICT.

ITEM.—*Paradise Reporter*, Aug. 30: A gentleman from this district reports everything prosperous in that camp, and says the mines are all looking well. The Ohio is producing a very rich ore, which is being sacked, and will be shipped to Salt Lake for reduction, next week.

ARIZONA.

ITEM.—*Prescott Miner*, Aug. 29: In the Crook ledge the tunnel is now in 80 ft and being driven day and night by three shifts, of two men each. The tunnel is five ft wide by seven ft high, and will strike the ledge in about 250 ft, at a depth of 200 ft from the surface. There is a shaft down 100 ft on the mine with a pay streak in the bottom four ft wide that goes in the neighborhood of \$30 to the ton.

ITEM.—*Weekly Star*, Aug. 28: In Tombstone district the Cincinnati claim has just had an immense ore body of rich carbonates opened up at the bottom of a 70-ft shaft. The Contention hoisting works are erected, and will soon be at work. At the Grand Central the 25-ft shaft at the north end is 8 by 12 ft in size and all on solid ore. The Luck & Cuss is being steadily and extensively worked in three different shafts of the present depth of 200, 100 and 20 ft respectively. Seven to eight hundred tons of good ore are out on dumps. The work on Tough Nut cuts in the gulch has been taken off on account of the rains, and concentrated on the deep shaft which contains a big vein and worlds of ore.

YAVAPAI MINING NOTES.—The Tiger mill is pounding away, day and night. Tip-top mill is running 12 out of 16 hours. Very rich ores are being raised out of the Black Warrior and Silver Prince shafts. Tunnels are being run into the Crook, at Crook canyon. Lively times at Seymour and the Vulture mill. Results of milling very satisfactory. The stream of bullion from the Tiptop mine is steady at \$35,000 to \$40,000 per month. Two quartz

mills are being erected in Big Bug district. The Central Arizona mining company's mill at Seymour is producing gold bullion to the satisfaction of its owners, who are about to increase the mill to 40 stamps. The Bradshaw mill, in Bradshaw basin, will soon be running on ore from the Loheno and other lodes. The Oro Bonito mill is working and paying well. The Cherry Creek mill will soon be ready to crush rock for hire. The Lynx Creek mill, running four arrastras on Lynx creek, is doing well. The 10-stamp gold mill in Big Bug district is almost ready to work, and another 10-stamp mill lately brought here is being erected.

COLORADO.

ITEMS.—*Georgetown Courier*, Aug. 28: The shaft in the Lulu lode, situated on Red Elephant mountain, 1,800 ft west of Boulder Steep, has reached a depth of 200 ft, and two levels are now being driven east and west, the first at 200 and the second 250 ft depth. The first level has been driven west 85 ft and shows more or less ore in the entire distance, the vein in places being 14 inches thick. The best ore is in the bottom of the level, which indicates that it has been run near the top of the pocket. The breast at present shows about six inches of ore and crevice rock mixed, which mills about 140 ounces. This level has been driven east of the shaft for a distance of 75 ft, the ore being shattered and consequently low grade. In places this level shows three ft of mixed silver, the mills from 40 to 60 ounces per ton. Between the two levels the shaft shows more or less solid ore all the way down, which mills from 150 to 300 ounces. East of the shaft for a distance of 20 or 30 ft above the second level there has been a cave which has exposed a fine vein of solid ore. The second level has been driven about 30 ft east and 15 ft west, the vein of solid ore exposed being about 10 inches thick. Some new mines have been discovered in the Silver Creek mining district, eight miles southwest of the sawmill in Poncha pass, and six miles from Poncha springs. They are silver veins in true porphyry and a number of them have been found to carry high grade ore. The principal ones are, the Mammoth with a 12-inch pay streak averaging 300 ounces in silver; the Olympic with 15 inches of pay ore that averages 100 ounces; the Maxwell with rich veins averaging 275 ounces; the Potucha with two veins of galena ore, 8 and 12 inches thick, averaging 25 ounces; and the Little Lottie, an extension of the Maxwell, with a pay streak six inches thick of 231 ounces ore. Eighty pounds of Mammoth ore sent to Leadville gave a return of 420 ounces.

ITEMS.—*Miner*, Aug. 23: In Treasure Vault and Glendale lodes, in the Clear Creek country, the vein has been proven a distance of 3,000 ft in length. The Glendale claim shows three ft of quartz wherever exposed, some of which assayed as high as 1,163 ounces of silver per ton. No. 3 lode of the Joe Reynolds' properties is yielding rich ore. The Cramer lease has ten inches of nearly solid ore, a late run of which milled 88 ounces for first-class ore on a 142 for second-class. The Peruvian mine, in Summit county, has three shafts and a crosscut over 200 ft long, has been driven to strike the lode.

ITEMS.—*Boulder News*, Aug. 29: In the Little Pittsburg the ore has got better, and the pay streak stronger as the tunnel has been driven in, so that in the breast there is at present nearly a foot of tellurium which runs from \$175 to \$200 per ton. The Prussian, on the same vein as the Little Pittsburg, makes an excellent showing of tellurium, 2 or 3 tons per week are shipped to Germany, the said assay high. On the west slope of the above claims a rich find has been made, specimens showing crystallized free gold and tellurium. At Jamestown the Overland mine has 1,000 tons already out of the mine, assaying 6 ounces in gold and 8 ounces in silver. The Buenos Ayres, a silver-bearing vein, runs from 100 to 136 ounces per ton.

IDAHO.

ITEMS.—*World*, Aug. 29: The Yuba tunneling company at Atlanta are now in with their main tunnel 1,200 ft and on a level with the great Atlanta ledge at a depth of 1,300 ft below the surface. Missions of the Yuba tunneling company are taking splendid ore out of the east extension of the Sub Rosa mine. They have 30 tons on the dump that they think is good for \$75 per ton. The Banner mine has been drained and the new tunnel connected with the old mine, which is in good condition.

MONTANA.

CELEDALE.—*Helena Independent*, Aug. 23: At the Hecla works and mines the crushers, blasts and 50-ton water jacket smelting furnace are now running. The production averages about ten tons of copper matte and bullion per day, the former being shipped to Germany, the latter to Omaha. The bullion carries about 450 ounces of silver per ton and the copper matte 300 ounces of silver and 50% copper. The incline on True Fissure is down 500 ft, and on Mountain Sheep 800 ft, the new mines yielding about 125 tons per week, and the new Atlantic with incline of 1,100 ft yields about the same number of tons. Inclines on the Olympic range of 200—3,000 tons are cribbed on dumps. A tunnel will soon be started in the ore of Lion mountain to tap mines at vertical depth of from 400 to 700 ft. A mine is being sunk on the Keokuk and Phil Shenon.

BELOMONT.—*Miner*, Aug. 28: The Belmont mill and mine, of the Silver Creek district, give employment to 60 men, all told. The Belmont lode, although considered gold-bearing, nevertheless carries occasional "horres" of rich ore, a species of cavorite whose acquaintance the mine managers are in no way likely to make. Some time ago a Frue vanter was put in below the mill, to operate on the tailings. Twenty tons of concentrates, worth \$150 per ton, have already been saved at a trifling cost from tailings which would have otherwise gone to waste. A pan is now being erected for the amalgamation of these concentrates, and operation will begin, likely, this week.

SILVER CREEK.—The following are the names of the mills of the famous Silver Creek district, with the number of stamps at work in their respective batteries: Penobscot, 40 stamps; Belmont, 20 stamps; Whippsworth, 10 stamps; Cotter & Hickey, 5 stamps; Magyar, 5 stamps; total number of stamps, 80. All the above named mills are employed in the reduction of gold-bearing ores, except the Cotter & Hickey, which is a mill for silver processing from a lode yielding a handsome in both silver and gold.

MANHOS COUNTRY.—A new district has been formed near the source of Barton gulch, where some valuable locations have been made of silver lodes. They are very rich. The recent discovery of some new leads in Summit district are developing richly in free gold. Red Bull district is now yielding more gold than it ever did. New discoveries and increased development are giving it to be one of the substantial and productive districts of the country.

NEW MEXICO.

ITEM.—*Grant County Herald*, Aug. 23: The mines at Lone mountain are showing better the more they are developed. All the miners there are content and doing well. The mill is giving good satisfaction and is kept busy day and night.

OREGON.

BAKER CITY.—*Bedrock Democrat*, Aug. 27: At the Virtue mine steady progress is being made in taking out the water. The Superintendent informs us that in two weeks the 400 level will be reached, and in four weeks the mill will be out to the bottom of the mine, when the sinking of the new perpendicular shaft will be commenced.

New Incorporations.

Requirements of the Age.

We publish herewith the substance of an address delivered by the Rev. Thos. Guard, at the Grand Opera House, upon the occasion of the opening of the Mechanics' Institute fair:

There has not been any dearth of exhibitions in our metropolis during the last few months. I cannot imagine a type of taste for which exhibitors have not most liberally catered.

There have been political exhibitions, and of these a greater variety than the creative genius of America had ever dared to produce; indeed, no less than a perfect quartette—soprano, alto, tenor, bass. I shall not venture to say which is soprano, and I shrink from suggesting which is the bass; nor am I prepared to say to what concord of sweet sounds this quartette may yet constrain us to hearken. The air around us is tremulous with melody, and the symphonic billows of this political quartette break in silver spray upon Mt. Shasta's slopes, blend congenially with the hideous howling of the Cliff-House sea lions, swell the cadence of the Vernal and Yosemite falls, and die into silence amidst the murmurs of the honey-laden bees that haunt the orange gardens of the City of the Angels.

And then there has been the far-famed Pedestrian Exhibition in the great pavilion of this Association. Who has not heard of that exhibition? From what classes of society were spectators not drawn, to witness the sublime feats of the contestants for the diamond belt? Who among us is competent to describe the extremely salutary influence of that pedal display? In what a chaste fascinating aspect it presented woman! What a winsome example it lifted to the admiring gaze of "our sisters, and our cousins, and our aunts!" What a refining agency was suggested to the lovers of American culture! In what an *economic* light it placed the female members of our families! "Hard times" may become easy of endurance if we can but train the limbs of our girls into speed of motion; and, hushing all the objections springing from their pure and gentle bosoms, urge them to the saw-dust ring and the voluptuous leers of lewd gamblers, where they may harter away the pearl of their womanhood for thirty pieces of silver.

Oh, yes! ours is a progressive age. At last we have reached our own exhibition. And I congratulate you on this auspicious occasion. Our exercises to-day are a sort of *prelude*, to which I have the honor of contributing a note.

I am to offer you a few thoughts, suggested by our annual fair. It is impossible for any but the most frivolously-minded to linger within the pavilion during an exhibition such as this without acquiring material for most remunerative study. Indeed, this is one of the many benefits which accrue from such an institution. It invites inquiry; it provokes discussion; it wakes the mind from stupor, and impels it to investigation; it excites the fancy; it regales the imagination; it refines the taste. And whatever elicits thought and compels the mind into meditative mood; whatever enlarges the comprehensive outlook, and strengthens the apprehensive grasp of the understanding; whatever augments our control over the activities of the mysterious spirit within; whatever gives us enfranchisement from the tyranny of the senses, and independence of the pleasures which materialism ministers; whatever lifts us into the region of pure ideas, and wings us for flight o'er the serene and luminous realms of truth and beauty; commands our most fervent gratitude, as an educator of the human race.

If you ask me what is the prime and most masterful thought suggested by my visits to "The Fair," I at once reply:

The Sovereignty of Man.

(1) Everywhere, around, above, I recognize tokens of this; I look upon the tribute which, as a sovereign, man has extracted from nature. The dominion is a noble, it is a vast, it is a varied one. Here in the exhibition are proofs of man's sovereignty over winds and over water, over light and over heat, over chemic and over mechanic energies. From the marching season and the timely rains; from the hidden wealth of mountains and from the wealth more real of the generous soil; from the products of the forest and of the flock, and of the field, and from the products of the far-re-sounding sea; man draws revenues and service. Lightning is his courier, and light his artist. Trade-winds waft his white-winged argosies, and snows gather on Sierra crests to swell the floods wherewith his ample acres shall be irrigated. Flowers, by their weird alchemy, transmute dew and gases into aromatic odors for his delight; and change sublimas and dull clays into bues emerald, purple, and roseate, wherewith to greet his kindling glance, as he moves out to gaze upon an inheritance, over which "far as the breeze can bear the billow's foam," it one day shall be true, man's nod is empire, and his footfall law. Silkworms spin for him; oysters secrete pearls for him; lime becomes marble and carbon diamonds for him; rocks are turned into silver, and plants become coal for him. Rivers leap to light from lofty fountains in the hearts of hoary hills, that, utilizing the law of gravitation, man may make them turn his ponderous wheels, and whirl his myriad spindles. The wild fowl "nurses" the plume that shall wave upon his victor helmet; and the cotton and the flax plant offer the fibers of which to fashion the banners beneath whose folds he shall move

forth to conquest; or repose unbarred amidst the fruits of his free and honest industry. *Force* guards him—sows, reaps, threshes, and grinds for him, as in ages past it toiled in fashioning his dwelling-place. *Art* breathes inspiration. *Music* reveals her mystic laws to his modulating genius. The block becomes a thing of beauty. The canvass glows with the tints and flush of life. Arch and pillar, capital and dome, spring from earth and soar to heaven, obedient to his all but necromantic touch. Homer, wrapped in his singing robe, wet with the dew of the morning of the ages, chants his immortal epic, to find in the broadening centuries a whispering gallery, round which his melodies shall swell in musical thunder,—Dante, gentle as he is sublime, tender as he is stern—a violet in the rift of an Alpine glacier; or, the "Victoria Regia" of the middle ages; and Milton, blind with excess of light, laden with the lore of classic and of sacred thinkers, clarified by waters of sorrow, and chastened by fires of fierce scorn, his harp upon his shoulder, daring the Seraphim to a trial of their strength of passion and their sweep of thought—these all proclaim the extent and opulence of the sovereignty of man—all are his: the true, the beautiful, and the good.

(2) This sovereignty is based upon and maintained by knowledge of, and obedience to, the laws of nature. In our age it is superfluous to attempt to prove the unity and universality of law. The truth is axiomatic. The gem and the snowflake are crystallized according to law. The cloud floats and the bud bursts into blossom in accordance with law. Atoms combine, birds migrate, tears are molded, and planets wheel, obedient to law. Logicians reason, poets create, and orators persuade by reverence for law. "Her voice is the harmony of the universe, her home the bosom of God." Man must rule nature, in stern and strict conformity to the "constitution of nature." And so faultless is the constitution that no amendments are possible. Not amend nature's laws, but, know them and obey them, is man's duty, and "in the keeping of them" prove "there is a great reward." Man can, indeed, unite those laws; can effect a combination of several of them, and by so much augment his power. And this is being constantly done. Every building erected is the result of combination of many laws of nature; every organ built is another result of such combination of law's forces; every telescope is the product of many laws in combination; every strong man is a concentration of laws selected from the chief departments of nature's immense domain.

This Makes Science a Necessity.

(3) For to rule you must know the subjects ruled—their numbers, their natures, the conditions of their existence and well-being. Ignorance is incompatible with efficient government.

One of the most important points to be secured by the civil ruler is this: that he know the temper and the habits and tone of thought characteristic of the people ruled. The great Chatham knew the English people; and this made him supreme in the councils and supreme in the affections of his countrymen, who loved to speak of him as the "Great Commoner."

To truly rule yourself, it is of highest importance that you study and seek to know yourself. Therefore, "the proper study of mankind is man." Nor less is this true of the sovereignty now spoken of. All the sciences were included, therefore, in the decree,—"Have dominion, replenish the earth, and subdue it." Study the properties of plants and shrubs, of flowers and fruits, grasses and herbs. *Botany* is here. Study the properties of animals, of fishes, of birds, of beasts: their habits, their foods, their instincts, so that they may be utilized for commerce, or for domesticated ends. *Natural History* is here. Study the secrets of atmosphere and water; of heat and light; of soils and rocks; and of the mutual influences of all these upon organic life. What is this but *Chemistry*? And so of the *Mechanical Sciences*, and so of the science of *Navigation*. This at once proclaims the sovereignty of mind, thought, intelligence; and embraces all the progressive acquaintance with the facts and the forces of creation, gained by man during his process through the ages past, and yet to come.

The clearer the mental eye of the sovereign, the better equipped for the scepter of his empire. *Thought* is the ruler. *Ideas* are the conquerors of all things: physical, political, moral, and religious. The man of most ideas,—the man who knows best how to express, and embody, the greatest number of the greatest thoughts, is, by "Divine right," fittest to rule.

Subjugation is Demanded.

(4) All sovereignty wielded by man hitherto has been preceded by struggle and subjugation. I cannot rule myself unless I subdue myself. Self-conquest prepares the way for self-government. Full off the struggle to subdue involves awe-inspiring efforts. The subjugation of the appetite and of the temper, and of the desires, of the tongue, of the senses and of the thoughts,—Ha! what battles are suggested by words like these. Marathon, Waterloo, Bunker's Hill and Gettysburg; these are but gala-day fights in comparison. No eye may have witnessed, no stranger have been cognizant of the strenuous, stern but sublime endeavor to put down and o'ermaster so as to rule the spirit with calmness and keep it in hallowed harmony. Only in the blaze of the great white throne, and when crowned by the all-seeing One at the last day, shall it be known how many the heroes whom history never emblazoned on her pages; whom

poets never lifted to fame by their imperishable odes.

The freedom of to-day is the fruit of struggle. Freedom of thought in society; freedom of opinion in religion; freedom of action in politics;—all secured by struggle. Tortures endured, blood spilled like water, life offered without stint, without complaint. But so the fetter melted from the bondsmen; so the tyranny of superstition hit the dust of irretrievable defeat; so the despotism of Autocrats dissolves and "leaves not a wrack behind." Even so God wills it to be in the sovereignty referred to in my theme. "Subdue it," as He points to the sea; and man builds his breakwater and floats his navies. "Subdue it," as He points to the morass; and man begins to drain it, and build his causeways o'er it. "Subdue it," as He points to the forest; and man wakes echoes from the primeval shades with his axes, and kindles fires around the venerable monarch of the woods. "Subdue it," as He points to the Sierra; and man cuts out his iron pathway o'er them, tunnels his course through them, and waves his flag of triumph upon their loftiest summits. "Subdue it," as He points to the lightning; and man plants his conductors to draw down and tame its fire, and spreads his wires that o'er them the invisible and fleet-footed force may bear his message. "Subdue it," as he points to the wild horse of the plains; and man puts a bit in the mouth and bridle on the neck of the steed, until "a little child shall lead him."

Labor Demanded.

(5) The struggle for existence and for sovereignty, implies and demands labor. Work is demanded, both in the study of the facts and forces of nature, and in the development of the physical resources of nature.

It were a grievous mistake to imagine that none save those who fling the shuttle, or drive the plow, are laborers, or workmen. Think you that the brave men who have gone forth to explore and discover the extent of the domain given to man for his possession, are not members of the guild of honest and noble workmen? Livingstone, Franklin, Kane, Baker, Stanley;—these not laborers as truly as the man who wields the hoe, and hews down the forest! No men have better right to their "spurs" than such knights as these. Think you that they who follow the comet, or foretell its approach; who bend over the crucible, and ply the scalpel; who untwist the sunbeam, and analyze the light-wave propelled by Sirius upon the shores of our small planet; that they who read the epitaphs carved upon the rocky tombs of fossil plant and Saurian monster; who watch the birth-bour of the tornado, and signal the moment of its advent of terror and desolation,—that these, and such as these, eat the bread of idleness, or sleep the sleep of the sluggard? Nothing is more remote from truth, than such a thought. Every furrow on their ample brows is the record of a conquest, as truly as that every crow's foot wrinkle round their eyes of unquenched fire is a scroll written over with fragments of "the fairy tales of science, and the grand results of time." Free from the law of labor man cannot hope to live. With cessation of the need of labor barbarism begins, and reversion to savagery becomes a law of life. Naturally, man is lazy. He loves the idea of "labor-saving machines." Scientists, perhaps, might tell us, that in this indisposition to work, we prove our ancestry back to the South American sloth. Be that as it may, it is not good for man that he be exempt from the law of labor. The more one ponders the matter, the profounder the conviction of the divinity, the dignity, and the blessedness of work. It has the approval of my reason, the sanction of my conscience, the well done of my God. Working, I develop my being; I restrain my animalism; I win self-mastery. Patience is cultivated; perseverance becomes a habit. Draining yonder marsh, I may be aided in draining one as sour within my own heart. Rooting out yonder briar, I shall be helped in checking the growth of a vice as pestiferous in the soil of my own spirit. And, knowing right well the drift and tendencies of my nature, the benign Father of all, "for my sake,"—for my weal, "cursed the ground," not CURSED LABOR;—the philosophy of which, it is not my business now either to discuss or to defend.

Again we say, labor is the law of life. All things living, on earth or elsewhere, move in harmony with it. From God, who worketh ever, upholding, renewing, restraining; consoling, inspiring, defending; bidding worlds from nothing into being, and feeding the fires of ever-burning suns, from age to age; nerving saints for heroic battle against wrong, and welcoming them from their fields of toil, or their furnaces of martyrdom, into quietness and assurance forever;—from this God, down to His tall angels, who now work in bearing up a little one along his path, lest he dash his foot against a stone, and again work in wafting the spirit of a pauper upon their unmoiling pinions, whither the storms of this world cannot travel, nor its mist of darkness float; down to the coral-builder that faints not, neither is weary in its toil masonic beneath bright tropic skies, and cheered on in its silent labors by the choral chantings of Pacific waves,—Labor is life—is gladness—is beauty. And let the thought be repeated and emphasized—the labor of life is a battle. It is a fierce strife. Vigilance ever demanded; forethought in ceaseless play. For floods challenge, tempests call in trumpet tone, and drought, and locust, and prolific weed-growth dare man to wrestle with and vanquish them. And if man were as wise as he might be—then should be bail the struggle

as his opportunity for achieving that "to which the whole creation moves"—"MORAL MANHOOD"—SELF-SOVEREIGNTY!

The peril in our midst is great in this particular: That work shall be deemed ignoble. But, in truth, in no land beneath God's generous sunlight is honest toil more honorable than in this free country. The spirit of gambling has been in our atmosphere quite long enough for the health of our sons and daughters. It creates feverishness, restlessness, impatience, contempt for slow, steady processes and deferred results and profits. We would move, but when swept by lightning express, or "two-twenty trotters." The old method of honest, intelligent, persevering, plodding toil, as that by which honor shall be won, competence gained, and well-being realized, may have served in generations past. But young Californian Americans cry out against all such "old fogyism."

No thoughtful observer can have failed to recognize in this fair an illustration of the laws of co-operation and division of labor. These products had never been, but for diversity of gifts in the endowments of men; diversity of adaptation as the result of those endowments; and then, union of all these, in endeavors to supply the wants of humanity.

Single-handed, single-hearted—bow feeble is man! What a narrow map of survey; what a superficial acquaintance with the facts within that circumscribed domain! What hope can be cherish of victory over nature's forces single-handed. The highest type of animal life presents us with the greatest diversity of organs and functions co-operating to one end. The loftier life, the greater the number of forces focalizing to sustain such life. The functions of the lowest living thing are fulfilled by one organ. Loftiest life is nourished by a score. Savage life, as contrasted with civilized, illustrates the same principle. It is before us most truly in our exhibition. There is the product of the workman iron and the workman marble. There is the flockmaster with his wool, and the grape grower with his wines and raisins. There is the manufacturer of blankets, and the producer of beaves, of butter, and of beet root. There is the spinner of steel wire and of bemp rope, by the former meeting the needs of our street car companies, and by the other supplying the demands of that extremely necessary adjunct to our civilization—the common hngman. There is the tooth extractor, with its pleasures of hope, and the toy for the infant just cutting its teeth. There are Cinderella slippers for fairy-footed belles, and there are the no less fair and fairy edifices, "castles in the air,"—called honnets. There are sweatmeats for "biling and cooing" lovers, and preserved meats for sorrow-cheeked, desiccated and melancholy bachelors. There are crystal goblets, from which to quaff that elixir of life, and home of living things, called "Spring Valley water;" and then there are brooms, and "combination mops," over which Mrs. Farington must shed tears of ecstatic joy, and large enough to sweep into limbo all the cobwebs that ever clustered in the antique corners of an old City Hall, and cleanse the filthiest floor o'er which the disgusted members of a political caucus expectorated their contempt and chagrin, in tobacco juice. Here are cradles, in which may be rocked into dreamland the future saviours of their commonwealth; and here are revolving lounges, upon which the fathers of these precious creatures may gyrate, as they study the problems of statecraft and of the Stock Exchange. Here are materials for the printing press, and for the circulation of opinions that are reformations in embryo, and revolutions in the germ. And here are organs and pianos—for man longs for rest, and yearns to forget his woes; and would fain voice his hopes, and antedate his immortality, in that ethereal speech called music. And here is our "gallery of the fine arts." For man is made for "the beautiful." Nor is he satisfied with the provision for his craving, furnished in the forms, and colors, and motions of creation. There is no stint, it is true, in nature's supplies. There is the tint of the fox-glove, and the gleam of the gem,—and the pomp of the cloud-storm, and the grandeur of the snowy peak, and the mirror-like repose of the land-locked lake, and the plumage of tropic bird, and the majesty of sunset, and the swell of the foam-wreathed billow, and the serenity of eve, and the valley all afire with morning sunbeams, steeped in pearls of dew. Yet, this is not enough. And the artist must extract from these their fairest, their purest, their noblest; and of the extract fashion scenes not more true to nature than they are true to the loftier ideals with which imagination loves to commune.

THE PERFECTION OF NATURE'S WORKS.—

Upon examining the edge of the sharpest razor with the microscope, it will appear fully as broad as the back of a knife—rough, uneven and full of notches and furrows. An exceedingly small needle resembles an iron bar. But the sting of a bee seen through the same instrument exhibits everywhere the most beautiful polish, without a flaw, hlemish or inequality, and ends in a point too fine to be discerned. The threads of a fine lawn are coarser than the yarns with which ropes are made for anchors; but a silkworm's web appears smooth and shining, and everywhere equal. The smallest dot that is made with a pen appears irregular and uneven; but the little specks on the wings of insects are not only found to be perfect and regular, but to often show elaborate designs of a detail which is the admiration of the microscopist.

Hydraulic Gold Mining in Georgia.

Going seven or eight miles up the Yahoola river, a dam was built where the stream rushes through a picturesque gorge, whence a small ditch six feet wide and six feet deep was led along the side-hill, in and out of all the curves, sometimes through a short tunnel, then across an aqueduct, here and there, wherever its level led it, at a grade of four and a half feet to the mile, 20 miles down to the mines. This is the main big ditch. It has two or three large branches, and there are other lesser ditches throughout the region, supplying separate isolated mines, but none have so elevated a head or carry so great a volume of water as this, and it is the best of them all. When first constructed, there were many flumes and trestles along its line. Some of the trestles were over a hundred feet high, of great length, and a constant expense to keep in repair. At one spot an attempt was made to cross the bed of the Yahoola where the height of the trestle would be 250 feet, and its length nearly half a mile. By a lavish expenditure of money the structure was carried to the height of 150 feet, when it was found that the lower timbers had already rotted out. The scheme was therefore abandoned, and the vast erection demolished, entailing a loss of almost \$200,000. Engineers say that, with all the appliances and force which could be brought to bear there, it would be impossible to build a high trestle as fast as it would decay at the foundations.

In place of this, iron pipes were substituted, and an inverted siphon made. The descent from the top of the hill is at angle of 45°, and is 215 feet in length; the pipes then cross the bed of the stream upon wooden supports a distance of 167 feet, and ascend the opposite bank 200 feet. The pipes are made of heavy boiler plating, and are 36 inches in inside diameter. Through them the water rushes with a pressure of nearly 100 pounds to the square inch at the bottom, and that is sufficient to overcome the friction and lift the column of water on the other side to within six feet (and perhaps nearer) of the level of its starting point. It was found not long ago that some men had been accustomed for a long time to shoot through these pipe sticks of cord-wood, cutting them on the mountain opposite their homes. Finally they got to running whole logs through; but one was too long and got stuck, which led to the detection of this labor-saving fraud. At other points subterranean wooden tubes of equal caliber, similarly arranged, conduct the stream across the valleys. One of these tubes is 1,500 feet in length.

Having got this tremendous "head" of water at their disposal by the completion of the ditch, stamp mills were built far below it in the valleys, at points suitable to the best diggings, and they were ready to begin operations upon the new system. The cutting having been opened at the brow of the hill, a reservoir is constructed, in which water from the ditch is allowed to accumulate to the amount of thousands of gallons, whence a side ditch, controlled by flood-gates, leads to the upper edge of the cutting. From the mine downward a channel is arranged, as precipitous as possible, leading directly to the stamp mill, where a room is open to its entrance. If now a torrent should suddenly be poured into the cutting, away up there on the edge of the mountain, which seems almost to overhang you, it is evident that all the loose material would be swept out and sent headlong downward to the bottom of the hill. What a natural fresbet would accomplish by accident is precisely what the miners do by artifice. They dig away all day at the loose soil and easily disintegrated rock, break up the larger fragments into small pieces and strew everything, good, bad and indifferent, in a careless pile on the floor of the cut. Then at sundown they gather up their tools, climb out of the diggings, and open the gates of the reservoir. A torrent sweeps through the mine, cleans out every loose rock and fragment of dust and hurls it down into the mill, where a rack catches all the coarse material and lets the water drain through into the much-tortured Yahoola. The whole product of the day's excavation has been deposited on the floor of the mill, half a mile away, ready to be shoveled under the stamps, which chew on it all night, and it has not cost a penny for transportation. —*Ernest Ingersoll, in Harper's Magazine for September.*

JAPANESE SPHERES OF ROCK CRYSTAL.—The difference between glass and pebble is that pebble is a better conductor of heat than glass, and therefore feels, like all other gems, colder to the tongue than their glass imitations. This is test No. 1; test No. 2 is to look for air bubbles; if with a magnifying glass you discover the minutest air bubble, it is certainly glass, as in natural stones air bubbles are never found. Test No. 3 is the hardness; a piece of a steel file will scratch glass, but it will not scratch pebble or other precious stones. Test No. 4 is polarized light; a piece of glass placed between the polarizer and analyzer of a polariscope does not show anything peculiar, while any part of a crystallized substance will show either variable colors or at least changes of light and darkness when its position is changed, the dark spots showing the direction of the axis of crystallization.

ELECTRICAL LETTER BOXES.—Among the recent applications of electricity is an attachment to street letter boxes, so arranged that if an attempt is made to rob the box an alarm will be instantly sounded at the nearest police station.

USEFUL INFORMATION.

SAPONIFYING MINERAL OILS.—A new process, says the *English Mechanic*, has lately been patented in England, which is said to prove satisfactory in saponifying the mineral oils. The patent applies not only to those oils which are found native, such as petroleum, but also to those that are obtained from coal, schist, asphalt and other minerals. In order to render such oils capable of saponification, they are first acidified by the addition of concrete fatty matter, either animal or vegetable, and the mixture is then saponified in the usual way by the addition of alkaline lye. The soaps thus produced may be varied in hardness and solidity according to the nature of the fatty matters and lyes employed; but in all cases they are powerfully detergent and disinfectant, and baths formed by them do not putrify even after use. Such being the general nature of the new and improved process, the manner in which it can be practically carried into effect may be best explained by a particular example: Assuming the oil to be treated to be rectified oil of petroleum and the concrete fatty matter stearic acid, the latter is melted in a water bath, and poured into the petroleum, which is at ordinary temperature, the stearic acid being added to the petroleum in the proportion of about 15 parts of the former to 100 parts of the latter by weight. After thorough mixture, by stirring for a short time, the compound can be saponified in the usual way. It is, however, of advantage to combine it, before saponification, with animal or vegetable fatty matter; a good proportion for such combination: two of the acidified petroleum to three of the fatty matter. Either soda or potash may be used to saponify this compound, producing a benzoin soap, which may be made hard or soft according to the alkali and the proportions adopted in the saponification.

REPEATING MATCHES.—A patent has been taken out for a repeating match—that is, a match that may be struck a great many times, and yield a light each time. The match consists of two rods of inflammable composition, placed side by side in two compartments, with a suitable case. In order to strike the light, a scraper is moved by hand along a platform across the open ends of the two rods. The scraper removes a certain quantity of its substance from each rod, and mixing these together the light is produced. One stick is composed of three parts chlorate of potash and one part of clay, thoroughly mixed and formed into a thick paste by the addition of water, then dried. The other stick is made of three parts amorphous phosphorus and one part of clay, prepared in the same manner.

CRYSTALS FROM CAST-IRON BY ETHER OR PETROLEUM.—On treating comminuted cast-iron with these solvents, on the spontaneous evaporation of the liquid, the author obtained acicular crystals, consisting principally of sulphur and absolutely similar to those extracted by the same process from meteoric iron. M. Berthelot, to whom the author had forwarded specimens of the crystals, stated that he had obtained similar bodies by the action of pure ether upon octahedral sulphur and upon anhydrous iron sulphides. It thus appears that even neutral solvents do not in all cases act by simple solution upon the bodies with which they come in contact, but effect also a chemical alteration. —*Scientific American.*

INCOMBUSTIBLE WOOD.—M. M. P. Folhart claims that he has discovered a method by which wood of any kind can be rendered incalculable. It becomes, as it were, petrified without any alteration in appearance. Intense heat chars the surface, slowly and without flame, but does not penetrate to any extent, and leaves the fiber intact, whereby in case of fire the fireman would have no occasion to fear that the materials on which they tread would give way beneath them, if this operation has been undergone by the wood composing the staircases, floors, etc.

CARBOLIC ACID FOR WEEDS.—Some of our exchanges recommend carboic acid as a destroyer of perennial weeds in lawns. The acid of the ebops is diluted and poured from a bottle into a hole in the crown of the plant, made by a pointed iron. We have found a drop or two of strong sulphuric acid sufficient to kill instantly such intruders in lawns as plantains, dandelions, etc. The carboic acid, largely diluted with water, is recommended for garden walks, applied with a brush or watering pot. —*Country Gentleman.*

A STRONG WATERPROOF AND FLEXIBLE CEMENT FOR JOINING SHEETS OF MANILLA PAPER TO FORM A BOARD. can be made as follows: Good pitch and gutta-percha (about equal parts) are fused together, and to nine parts of this are added three parts of hoiled oil and one-fifth part of litharge; continue the heat with stirring until thorough union of the ingredients is effected. This is applied hot, or cooled somewhat, and thinned with a small quantity of benzole or turpentine oil.

TO SOFTEN PUTTY.—Slack three pounds of stone quicklime in water, then add one pound of pearlash, and make the whole about the consistency of paint. Apply it to both sides of the glass, and let it remain for 12 hours, when the putty will be so softened that the glass may be easily taken out of the frame.

A NEW PRESERVATIVE COMPOUND.—It has been found that the double borate of potash and soda has antiseptic properties. The compound is made by dissolving equal quantities of chloride of potassium, nitrate of soda and boric acid; filter the solution, evaporate to dryness, and keep in a tight bottle, as the salt becomes wet in the air. It is claimed that this salt has no effect on the smell, taste or healthfulness of the substances to which it is added. It has been tried for preserving meats, making sausages, butter and for tanning skins. Added to milk it will keep for a week; also added to beer or wine it retards the deterioration to which the inferior kinds of these drinks are subject.

IMITATION MEERSCHAUM.—Imitation meerschaum pipes are now manufactured from potatoes in France. A peeled potato is placed in sulphuric acid and water, in the proportion of eight parts of the former to one hundred of the latter. It remains in this liquid 36 hours, to blacken, is dried with blotting paper and submitted to a certain pressure, when it becomes a material that can be readily carved. The counterfeit is said to be excellent. An imitation ivory, sufficiently hard for billiard balls, can be made by still greater pressure. A resemblance of coral is obtained by treating carrots in the same manner.

PURIFICATION OF MERCURY.—The mercury is shaken up with an equal volume of a solution of five grammes potassium bichromate in one liter water, with the addition of a few c. c. of sulphuric acid, the operation being continued till the water becomes of a pure green. A strong current of water is then introduced into the flask, which washes away a green powder. This process is repeated if needful, and the mercury is finally agitated with distilled water till its surface remains perfectly bright.

GOOD CEMENT.—Gutta-percha cuttings are very useful for the laboratory. By dissolving them in benzols, and adding a little carmine or any other pigment, a solution is obtained which, when brushed on the cork and neck of a bottle, forms a tight-fitting cap, impenetrable to air, dampness, alcohol or acids, and can be taken off without difficulty.

POSTAL CARD INK.—An excellent invisible ink for postal cards can be made by diluting sulphuric acid with fifty times its volume of water. A slightly acid fluid is the result, which does not injure a quill pen. The message is developed by holding the card over any convenient flame—that of gas or spirits for example—or by laying it on a hot plate.

CURE FOR BURNS.—An iron foundryman recommends powdered pine-wood charcoal as "a never-failing, grateful, and speedy remedy" for burns and scalds.

GOOD HEALTH.

BLOOD EXAMINATION IN DIPHTHERIA.—Prof. Bouchut made daily enumerations of the blood corpuscles in all the cases of diphtheria that came under his observation within a period of six months, the number of analyses amounting to 177, and from the results obtained he has deduced the following conclusions: In severe septicemic, or malignant diphtheria, there is always an acute leucocythemia or increase of the white corpuscles of the blood, which increases as the disease progresses, and diminishes when convalescence sets in. On the other hand, in the mild cases of diphtheria without septicemia, there is no leucocythemia, and the children always recover. In 24 cases studied day by day through the whole course of the disease, the number of white globules varied between 5,000 and 10,000 in 12 out of 93 analyses, and between 10,000 and 100,000 in the other 81, the average being 26,824. Prof. Bouchut insists on the necessity of daily examinations of the blood, as the number of white globules may be normal in one day and greatly increased in the next. He claims that valuable prognostic data may be gathered from the examinations, a rapid increase of white globules indicating the occurrence of septicemia, and pointing almost positively to a fatal termination, while a persistence of the normal relations between the red and white globules indicates a mild form of the disease, and almost certain recovery. —*Medical Record.*

IODINE IN THE TREATMENT OF MALARIAL FEVER.—In corroboration of Dr. Willbrand's assertion that iodine is a specific remedy for malarial disease, comes the evidence of Dr. J. W. Wadsworth, Saltillo, Mexico, who has treated over 300 cases of intermittent fever with this drug. He has records of 260 of these cases, many of them being chronic cases extended over various intervals of weeks or months. In the severe cases, 10 to 15 grains of quinine were given at first, followed by compound tincture of iodine, M. x. to M. xv.; in the severest cases arsenic was added. In every case the paroxysm was arrested within 24 hours, and 12 doses, or four days of treatment, were sufficient to guarantee a cure, with the exception of eight relapses, six being on the 14th day, one on the 21st, and but one on the seventh. In not a single instance, though under the most miserable hygienic surroundings, did there occur a failure to effect an immediate cure, when the medicine was taken as directed. Quinine and arsenic have often failed the writer, but iodine never. —*N. Y. Medical Journal.*

POISONED BY NICOTINE.—A rather unusual case of poisoning by nicotine occurred lately in a Parisian suburb. The victim, a man in the prime of life, had been cleaning his pipe with a clasp knife; with this he accidentally cut one of his fingers; subsequently, but as the wound was of a trivial nature he paid no heed to it. Five or six hours later, however, the cut finger grew painful and became much swollen; the inflammation rapidly spread to the arm and shoulder, the patient suffering such intense pain that he was obliged to betake himself to bed. Medical assistance was called in, and ordinary remedies applied ineffectually. The sick man, questioned as to the manner in which he cut himself, explained the use to which the pocket-knife had been applied, adding that he had omitted to wipe it after cleaning his pipe. The apparent mystery that surrounded the case was thus cleared up, and, as the patient's state had become alarming, he was conveyed to the hospital. Upon his admission, the doctors attached to the institution declared that in the immediate amputation of the arm lay the only hope of saving the patient's life. The poisoned member was therefore amputated; but, in spite of the promptitude with which this operation was performed, the man lies in so precarious a condition that the chances of his recovery are said to be slight. —*Parisian.*

BRIGHT'S DISEASE AND ICE WATER.—A Baltimore druggist of experience and ample opportunity for observation, has advanced the idea that Bright's disease is attributable to the immoderate use of ice water and cold drinks. He cites the fact that the people of this country use 90% more ice in their drinks than the people of any other country—the inhabitants of Greenland not excepted. We have 75% more of Bright's disease. He cites the fact that the wine-drinking countries of Europe are comparatively free from the malady. Travelers have observed and commented upon the prejudice which seems to exist against ice water and iced drinks in all countries outside of the United States. The Englishman and the German fairly shun ice, though placed in easy reach of boundless quantities of it, and a Frenchman who sips the light wines would as soon think of taking an emetic as of chilling his stomach with an iced draft. Our drug friend points to the fact that Bright's disease has kept pace in this country with the increased consumption of ice, and claims that before ice became a common household necessity the malady was scarcely known among physicians. There may be something in this theory. —*Baltimore Gazette.*

HYGROMETRIC INFLUENCE OF TREES.—From some observations relative to the comparative influence of leafy woods and resinous woods on rain and the hygrometric state of the air, it appears that pine forests have a much greater influence on the hygrometric state than others; so that if the vapors dissolved in the air were apparent like fogs, we should see forests shrouded in a large screen of moisture, and in the case of resinous woods the envelope would be more pronounced than in that of leafy woods. Pines retain in their branches more than half the water which is poured upon them, whereas leafy trees allow 50% of the precipitated water to reach the surface of the ground. It is suggested, therefore, that in planting with a view to oppose inundations, it would be advisable to choose by preference resinous trees, as offering a better covert.

TO SAVE FROM DROWNING.—Never approach a drowning person from the front, but take him from behind by the hair, and never allow him to grasp any part of your body if you can possibly avoid it. Should he do so sink at once to the bottom, when he will release his hold on you. Only a good swimmer should attempt to rescue a drowning man in deep water; for a novice to try it is to imperil a second life with little chance of saving the first. Better hasten to secure a rope or a pole, or plank, which throw to the person in danger. This will give him a better chance of escape. If possible, let one going to the rescue have a rope tied under his own arms and held by some one on shore, or tied securely to some firm object. Young swimmers should use great caution.

ARSENICAL DOLLS.—A shopkeeper in a small place not far from Berlin bought a doll dressed in a green muslin frock, from a peddler for his child, aged one year and a half. The latter repeatedly put the doll into its mouth, as babies often will do; and a few days later showed very grave symptoms of some illness which the doctor could not define till he happened to cast his eyes on the doll. The frock was immediately sent to the next chemical laboratory, where it was found to contain a quantity of arsenic sufficient to injure even an adult. The police succeeded in discovering the peddler and the name of the firm where the doll had originally been bought. —*American Med. Bi-Weekly.*

TARTRATE OF MORPHIA.—Dr. John E. Stewart, in the *Edinburgh Medical Journal* for March, advises the use of tartrate of morphia as the best preparation of the alkaloid for hypodermic injection. It is a white powder, not unlike hydrochlorate of morphia, forming a milky solution in cold water, but a clear one in hot water, in the proportion of forty grains to the fluid ounce. It is claimed that the solution is perfectly unirritating, does not need filtering or neutralizing, and keeps fresh and unchanged for any length of time. It is recommended also for administration by the mouth.

The Week.

Information derived from various sources indicates continued activity and prosperity in the mining business. There is scarcely a county in the State that is not continuing its developments of precious mineral resources. Ledges of good paying ore are found in many unlooked-for localities, while old mines have been reopened and found rich enough to justify the outlay of capital for machinery and other improvements. The movement is quiet, but is nevertheless assuming huge proportions. Everything argues a return of mining prosperity upon a more solid basis than that of mere speculation. The mines are being worked for what they will yield in actual output and not used as paper mines. The outside States and Territories are making efforts to attract capitalists by fabulous assays of small specimens as samples of millions of tons. Inaccessibility afflicts many mining localities largely advertised, and numberless mines, each of which, from reports, contain enough solid gold and silver to double up the world's supply, are offered in market at wonderfully low figures.

Maine, Virginia, Georgia, Arkansas and Iowa from late accounts seem to be advancing in the scale of gold and silver-producing States. Nova Scotia likewise desires it to be distinctly understood that there is gold and silver within her borders.

The Philadelphia mint during the month of August coined a total of \$2,233,497, to \$3,720,000 coined by the San Francisco mint. Bullion deposits for August at the San Francisco were 134,558 ounces of fine and crude gold, and 163,601 ounces of silver. There was in addition 320,870 ounces of crude silver deposited for refining. The enormous amount of gold coin flowing to the United States from Europe suggests the possibility of a revival of prosperity which is undoubtedly needed. We have labored and waited and are now beginning to get a return from our bread cast upon the waters.

The Golden Harvest.

There seems to be a disposition on the part of some Eastern mining journals to underrate the mining capacity of California. And we have noticed in connection with this spirit a great desire to exaggerate the value and output of mines in other States and Territories, which are to a great extent controlled by Eastern capitalists, or in which the East is directly interested, by reason of contiguity or marketable nearness.

In early days, when California was dependent on the East for supplies, there was none of this spirit manifested. On the contrary, California was the Utopia of the predecessors of the present mining journals. But since California has become self-supporting and independent of outside markets, the current of opinion concerning her prospective brilliant future is sought to be diverted into other channels.

From a business point of view it is, perhaps, policy to seek new advantages when old ones have been found unremunerative, but in so doing it is unnecessary to exhibit sentiments of jealousy, so far as to depreciate that which the world knows is increasing in value instead of diminishing. We are intrinsically cosmopolitan in the broadest sense of the word, and have no jealousy. Our prospects forbid it. We welcome all capitalists who come to this coast, and lay bare to them our resources, keeping nothing in the background. Our mines possess an intrinsic value, and if we do not throw upon the market, at one transaction, railroad stock to the amount of \$76,000,000 it is because we have more solid and certain investments.

Our Mono county mines are not dependent upon sensational articles and extravagant assay for their success. The heavy bodies of rich ore now in sight, the new discoveries being made in the opening up of veins and ledges, sufficiently demonstrates the true value of that region, when we also consider the energy now displayed in working the mines. In the Bloody Canyon district, on the western slope of the Sierras, careful prospecting has developed rich ledges. The Golden Crown shows an assay of from \$143 to \$201 per ton at a depth of four feet, with a ledge 25 feet wide. There are many other locations, and croppings can be traced a distance of four miles. The ores are called antimonial silver ores, and grow free as they go down. With every advantage in the way of wood and water, this district will add largely to the wealth of Mono county. The wealth of Placer county has hardly been diminished by former mining operations, and is now on the point of being developed by Eastern capitalists, who propose to work on the middle fork of the American river on a large scale and sure financial basis. The old quartz claim near Humburg canyon has been re-located, and good looking rock is being taken out. The old Pioneer ledge in the same vicinity is about to be tapped by a tunnel, and the rich rock taken out through it. Machinery has been put up on the West Damascus Gravel claim, at the head of the north branch of Shirltail canyon, with a view to go to bedrock. Everywhere in Placer county renewed energy is being displayed in developing and working claims which were supposed to be worked out, but which are now known to have been merely skimmed.

In Sierra county new and rich developments have been made at Poe's camp. Ledges of rich ore are abundant, assaying \$60.27 gold and \$13.15 silver, and from two and one-half to six feet in width; with plenty of water and timber, the prospects of this county in its mining capacity bids fair to come up to the standard. In addition to precious minerals, it may not be amiss to mention an immense ledge of marble about five miles from Meadow lake, which has an average width of 390 feet by one mile in length.

Nevada county is increasing in mining activity, particularly Lowell Hill, which is in a prosperous condition, with 75 men employed in drifting the various claims. Other localities in this county present an improved condition of things. The miners of Butte county are engaged in cleaning up, with exceedingly good results.

Los Angeles county contains gold-bearing ledges; one in Shrewsbury canyon near Anaheim is claimed to be very rich. Placer mining at Lytle creek remunerates at the rate of from \$6 to \$7 per day. The silver ore taken from Silverado, and assaying as high as 80 ounces per ton, is very similar to the Leadville ore, and requires the eye of an expert to detect any difference.

Throughout the length and breadth of the State of California, an unusually careful prospecting has lately divulged resources in precious minerals which have been entirely unlooked for. The assays that have been made indicate a reasonable credible amount, which the output verifies and exceeds in many instances. Our local mining journals present none of the exaggerated, sensational articles so common to many regarding outside localities. There is more reserve on their part, having learned by experience that deception brings many sorrows. The reason of the activity displayed in the development of our mines cannot be attributed to any speculative frenzy, but to a well settled purpose of making our mining interest a safe, paying industry. Improved methods of working ores, and extracting gold and silver from those that are refractory, has all to do with the re-opening

of abandoned claims, and the facilities for working have increased so greatly that miners have been urged on in their endeavors, until valuable discoveries have been made, and new and rich ledges added to the already long list. If Eastern capitalists are willing to believe the enormous assays that are made in the ores of Utah and Colorado, which vary from \$50,000 to \$192,000 per ton, and invest their money, they have that constitutional privilege. But when capitalists are beginning to learn that these sensational assays drop to \$30 to \$40 per ton under the stamp, at an expense almost equal to the reality, and prefer to engage in the more satisfactory mining interests offered in this State, where opportunities are so much more favorable, we certainly have the right to argue against the jealous spirit that seeks to underrate what has not been exaggerated, and expose the impolitic plan of rule or ruin where control cannot be had.

Mining Decisions.

In 1871 the New Idria Mining Company applied for a patent upon 480 acres of mineral land situate in Fresno county, California. The application was rejected because, first, some of the necessary steps in the case were taken in direct violation of the orders of the proper officers of the Interior Department. Second. The evidence was defective in not showing that the proper notice and diagram were posted upon the premises, and in not identifying the claims alleged in the petition or advertisement. Third. There was not sufficient proof of the citizenship of the claimants, and the amount of land claimed exceeds that authorized by law. The mines claimed were alleged to be situated within the limits of the Rancho Panoche Grande, and the right to a patent on behalf of the New Idria was questioned both in Congress and in the courts by William McGarrahan, the alleged owner of the rancho. The Supreme Court, however, in 6 Otto (U. S.) decided that McGarrahan had no right to any of the land under the Panoche Grande claim, as it was fraudulent and invalid. Pending the McGarrahan contest the Surveyor-General of California, and the Registers and Receivers had received instructions from the Interior Department not to receive any application for mineral lands within the boundaries of the Rancho Panoche Grande. Despite these instructions the Surveyor-General and the Register and Receiver at San Francisco, caused a survey to be made of the tract claimed by the New Idria company, and received the application to purchase the same, publishing the notices required by the act of July 26th, 1866, and received payment therefor.

This was the first objection for rejecting the application for the patent. On review it was proved that the mineral land claimed was not within the rancho lines, and hence the departmental instructions had not been disobeyed.

The claim of 480 acres was in excess of the quantity that could properly be located by the parties from whom the New Idria company derive title. The location was made in supposed conformity with the rules and regulations of the San Carlos district, adopted Dec. 4th, 1854, which, however, authorized a person or an association to hold only 160 acres of land bearing silver or quicksilver ore. The original locators, Pitt, Collins, and Balenger, supposed they could take separately 160 acres each, or an aggregate of 480 acres, which they could not do, but only to the extent of 160 acres in all. The New Idria deriving title from them could not acquire any greater rights than were possessed by the original locators, and hence Secretary Schurz agreed with the decision of 1871, in this respect.

The defect in proof of citizenship was cured by the mining act of May 10th, 1872, which in the case of a corporation is made by filing a certified copy of their charter or certificate of incorporation.

The evidence, however, was still defective in not showing the date on which the proper notice and diagram were posted on the mine, and the date on which it ceased to remain so posted. The application for a reconsideration of the decision of Aug. 4th, 1871, and the issuance of a patent to said company for the tract claimed, was therefore denied by Secretary Schurz, July 26th, 1879.

In the case of Sayer *et al.*, vs. The Hoosac Con. G. and S. M. Company. The plaintiffs presented an adverse claim to the application of defendant for a patent for 1,500 linear feet of the "Dolly Varden," Secret Canyon Mining District, Eureka, Nevada. It appears that the 60th day of publication of notice of the application fell on Sunday, September 16th, 1877, and that at 10 p. m. on the previous day, Mr. Sayer presented his adverse claim and tendered fees to the Register of the Land Office, who refused to receive either. That on the following day, Sunday, Mr. Sayer again presented his adverse claim to the Receiver, who accepted it, filed it, and received the fees for the same. On contesting the claim, the Commissioner of the General Land Office decided that the adverse claim having been filed on Sunday a *dies non*, it must be regarded as having been filed on Monday, Sept. 17th, one day too late and rejected it. On appeal, however, Secretary Schurz held that in the absence of a law to the contrary, an adverse claim may be filed on Sunday, or out of office hours, if the local officers are willing to receive it, and accordingly reversed the decision of the Land Office.

The World of Improvement.

Our exchanges are filled with improvements, in the economical and practical devices which have been adopted by the mechanical and scientific world. Mons. Tellier, a French engineer, read before a late session of the French Academy of Sciences a paper on a new method of employing steam in engines. Constructors have hitherto aimed at keeping the steam as dry as possible. M. Tellier, however, admits heated water direct into the small cylinder of a compound engine, and claims in this way to generate double the quantity of steam with the same amount of coal, and obtains this apparent paradoxical result from the fact that the formation of steam no longer takes place in the boiler, but in the cylinder of the engine, for which reason, the disturbances inseparable from ebullition is no longer to be feared.

The inventor states that by this means the highest useful degree of heat can be obtained without excessive pressure, and that the condensed steam can be brought to reproduce effective steam at 234° Fahr. It is calculated that the best compound engines constructed on this principle will not consume more than 1 pound 12 ounces to 2 pounds 3½ ounces of coal per horse-power per hour.

Russia has had constructed for artillery, divisible guns, which can be divided into several parts for transportation. Experiments with small calibre guns have led to the construction of large calibres to be used for mountainous regions.

A ship canal is contemplated across the peninsula of Florida, for the accommodation of ships bound to and from the various sea-ports on the Gulf of Mexico, and to avoid the shallows and dangers of the Bahama channel. The canal will start from Cedar-Keys, on the gulf, and proceed in a straight line to a point on the Atlantic between Jacksonville and St. Augustine.

The value of aluminium in telegraphy has been for some time well known, and has attracted special attention from the fact that it possesses double the conducting power of iron, and can be drawn into extremely fine wires for various purposes. Its high price has heretofore been an obstacle in the way of its general use. A German exchange says it can be produced in large quantities, and at small cost, by reducing it from the cryolite of Greenland in smelting works by means of silicic iron or zinc ore.

The digging of the canal from Cronstadt to St. Petersburg is progressing so rapidly, that the Russian government has been assured that vessels of light draft will be able to reach the capital by next summer. Its depth will be 30 feet.

Several months ago, M. Thallon constructed a new spectroscopic, containing compound sulphide of carbon prisms, by means of which he effected a very much greater dispersion of light than had been attained previously. With it he has produced a remarkable map of the solar spectrum, which contains about 4,000 lines, in a length of 33 feet. The well-known map of Angstrom contained 1,600 lines in a length of about 12 feet.

Leclanche's battery has been improved by dispensing with the porous vessel heretofore used. It has a high electro-motive force and low internal resistance, and is a useful battery where not used on a closed circuit, or where the circuit is often closed.

A series of experiments with the Westinghouse brake have been lately made on the North Eastern Railway, England, with a view to determine the question of the friction of rolling bodies, and to test the value of the friction valves. A train going at the rate of 50 miles an hour was brought to a standstill within 200 yards. Another, going at 60 miles per hour, and a pressure of 70 lbs on the inch, was stopped in about 200 yards. The experiments were highly satisfactory. The Hollway process of using sulphides as fuel, heretofore described, is causing considerable discussion in Europe on account of its great economy.

In Paris, France, the animal and vegetable refuse from markets, and refuse of all kinds, has been calcined, and forms what is known as "Paris charcoal." A furnace for that purpose has been designed by an Eastern inventor at Stamford, Conn., for utilizing all these waste products. The mineral matters melt and form vitreous scoria, which flow outside, where they are converted into powder or fine sandy grains, or, if desired, converted into mineral wool.

American machinery continues in favor in Europe, particularly in Russia; also in South America. Locomotives, in particular, being in demand in Russia. European journals are filled with complaints concerning the influx of American machinery and products, and many plans are suggested to counteract them, but nothing has yet occurred to etay the importations.

An outcry has been made in England because of railroad discrimination in favor of American freights.

THOMAS W. BOOKE & Co.'s sheet iron and tin plate works near Cardiff, Wales, in constant operation since 1740, have been closed, throwing 1,500 persons out of work.

In San Francisco half dollars are quoted at 99½ buying, 99½ selling; trade dollars, 97 buying, 98 selling; Mexican dollars, 98 buying, 98½ selling.

The Victoria Regia.

The reigning queen of water lilies, shown in the engraving on this page, is of interest, both for its rank in the plant kingdom, and from the fact that it is now flourishing in California waters, having been successfully grown from the seed in the Golden Gate Park Conservatory in this city. A large artificial pond has been especially devoted to the fine plants secured, and they are now in vigorous growth of leaf and flower, the pride and admiration of San Franciscoans.

The Victoria Regia leaves are from six to eight feet in diameter, and the stem which bears them up is a hollow tube as large round as a stout woman's wrist. From the stem ribs shoot out which are two inches in depth and regular compartments are formed by intersecting ribs, resembling nothing so much as the frame work of a house. Spines project downward from the ribs, which are very sharp, necessitating wary handling. The leaf is green on the surface, and a purplish red beneath. The fleshy part is very thin and delicate, so much so, indeed, that the least impression will puncture it, while the leaves as a whole, thanks to the compartments underneath, which are filled with air, is very buoyant and capable of sustaining astonishing weight. A healthy baby 12 months old may be laid on one of them with security, and a plank stretched over two of them will bear up easily a full grown man. Its growth under the water is exceedingly interesting, as each day the leaves shoot out and make for the surface so fast as to create the delusion that one can see them moving or lengthening. Around each leaf, when fully developed, is a rim, which gives it the appearance of an immense floating dish. A niche or opening in this rim is a curious natural provision against disaster.

The flower of the great queen lily possesses many interesting features. It is from 10 to 12 inches in diameter. It lasts in perfection only two days, but the rapidity with which they succeed each other on a healthy plant makes amends for their brief existence. They bloom only at night. About twilight the petals open with a sudden jerking motion, one after the other, and close up promptly at daybreak. On the first day the flower is pure white, which changes on the second to an exquisite shade of rose pink. These flowers are very rare even in England, the country of their adoption, and £60, or \$300, is a moderate price for a fair specimen.

A lady of our city, Mrs. Anna Gettz Lucas, has made an especial study of the Victoria Regia, having ably reproduced the flower in wax. She has also compiled many interesting facts from the literature of the lily, and from her writings we shall take the following facts: The Victoria Regia, though indigenous to the climate of tropical America, growing in its magnificent beauty in the river Amazon and its tributary streams, is claimed as an English production, was named for its reigning Queen, and brought to the Royal Gardens at Kew; successfully cultivated also at Chatsworth by the Duke of Devonshire early during Victoria's reign. Its original discoverer was a German scientist named Henke, who found it growing in the marshes beside the Rio Mamore, a branch of the Amazon river, as early as the year 1801. Sir R. H. Schomburgk made a scientific visit to British Guiana, January 1st, 1837, and while sailing in a canoe up the river Barbioco, he was astonished to see, for over a mile of water, that the whole basin of the river was overspread with huge, round, curiously margined leaves and hundreds of magnificent, white and rose-tinted flowers, each measuring over a foot in diameter, scenting the whole atmosphere with a rich perfume like the pineapple. The natives called it "Y'repa," or Water Platter. The plants at Kew flowered in 1851, and between June and November produced 61 flowers.

The root is a large spindle-shaped tuber, with bundles of fibrous rootlets attached, which appear with every bud and leaf. The leaf is a bright green above, and a dull crimson below, with a rim several inches in width. The ribs are very prominent, almost an inch high and are eight in number, with similar ones branching off from them. The stem is in the center of the leaf, fully an inch in thickness, and has a brown, thorny appearance. The leaf is produced in a cycle of five. Twenty-five or 26 leaves appear before the flower bud. The leaf is from 10 to 13 feet in size; the flowers from 12 to 18 inches.

The flower stem is over an inch thick near the calyx, thickly studded with thorns about an inch long. The calyx is four-leaved, upwards of seven inches long and three inches broad, thick at the base, creamy white side, reddish brown and thorny outside, measuring from 12 to 17 inches in diameter. The pistils and stamens are numerous, the stamens growing like pointed scales around the pistils, the outside row, 30 in number, forming a crown around the rest. The color of the stamens is a brilliant yellow tipped in crimson. The flower petals

are from 50 to 60 in number, or three distinct sets, each growing smaller near the stamens. The first row next the stamens are of a brilliant rose color, spotted and flecked with crimson. The fruit, when ripe, is half as large as a full-sized human head, and is full of seeds. The natives of South America call it "mayz de l'agua," for from its seeds a farina is produced from which a paste cake is made, which they consider a luxury.

The first flower raised in the United States was at Springbrook, the country house of Caleb Cope of Philadelphia. His plants were raised in 1851, and the same plants lived for several years. One of them flowered 200 times. The plant was exhibited in 1865, near the Central park, New York, and during that summer produced 70 flowers.

The plants now growing at the Golden Gate park, seems strong and vigorous, likely to produce magnificent flowers, the conditions of its climate being favorable to its growth. It is grown from seed raised in London. We are indebted for the specimens now on exhibition at the Fair to the kindness of W. S. Munroe, the gardener at the conservatory.

Popular interest has been greatly increased in the plant from the fact that large leaves, cut from the Park stock, are now shown in a tank at the Mechanics' fair in this city, and attracted much attention. When the flowers are opening at the Park the conservatory is kept open until midnight and lighted so that the people can visit the lily queen. Her votaries have been many, and Victoria Regia may be proclaimed the belle of the hour.

Coals and Lignites.

In speaking of the coals of the North Pacific coast, they have usually been called lignites, to distinguish them from the coals of the carboniferous period, mined in Ohio, Illinois, Pennsylv-

THE VICTORIA REGIA AT GOLDEN GATE PARK, SAN FRANCISCO.

vania, and Great Britain. The *Daily Astorian*, published at Astoria in Oregon, says the name is an unfortunate one, because while the word lignite implies that the coal is of woody origin, it is now proved that these coals are not formed from wood to any greater extent than are the coals of the carboniferous period. Nor are they inferior coals, as sometimes designated. Coals of every quality and for every purpose can be found in the so-called lignite coals of the North Pacific. Vancouver's Island, good gas coal; Seattle, excellent grate and parlor coal; steam and parlor coals are found at Mount Diablo; while at Wilkinson, good blacksmith coal is obtained. Bituminous, semi-bituminous, and even anthracite coals are found in this region, all in the same lignitic period. Within 23 miles of Astoria, south, exist large veins of coal as good as the Sydney coals for steaming, and better than Seattle or Coos Bay for grate and parlor use. The *Astorian* proposes hereafter to drop the word lignite as too poor a name, and speak of these coals by their right name—coals, of the best quality.

SOUTH YUBA.—A tunnel is being constructed through a point of land on the south side of the South Yuba river, Nevada county, Cal. A mining flume is to be placed in it for washing the tailings continually passing down the river from the claims above. The tunnel is of a capacity sufficient to carry the entire volume of water and gravel passing through the flumes of all the mining claims discharging into the river above it. In addition to the tailings, a large portion of the river bed is to be laid bare and made available for mining purposes. The large amount of water, boulders, etc., prevented operations in early times, beyond demonstrating the fact that very rich pay dirt existed. The quantity of tailings is immense, and said to be rich.

SINCE the yellow fever broke out at New Orleans, July 22d, there have been 17 cases and five deaths.

Technical and Industrial Education.

SOME points made on this subject by our exchanges are worth the consideration of all interested in the solution of the educational problem. The subject of education in relation to its bearings upon points of public as well as private utility has enlisted many in the cause of the technical part of it, as a solution of many of the difficulties which are attendant upon the existence of a large unemployed class of citizens, or whose employment is unremunerative. Machinery is doing our drudgery for us, and now man, lifted by it out of the slavish toils to which he was accustomed by the introduction of labor-saving and automatic machinery, must either elevate himself to a higher standard of skill or fall back into utter degradation. There is hardly any medium, and hence the importance of an industrial schooling.

The advantages of technical education have been made more apparent in Europe than in the United States, because of the greater difficulty in securing remunerative employment. The ability of labor counts for little. Skill is at a premium everywhere.

Mr. Huxley says: "If a lad in an elementary school showed signs of special capacity, I would try to provide him with the means of continuing his education after his daily working life had begun. If in the evening classes he developed special capabilities in the direction of science or of drawing, I would try to secure him an apprenticeship to some trade in which those powers would have applicability. Or, if he chose to become a teacher, he should have the chance of doing so. Finally, to the lad of genius, the one in a million, I would make accessible the highest and most complete training the country could afford. Whatever that might

Progress of the American Silk Industry.

It is beyond question that the silk manufacturing industry of this country is making notable progress. As we have stated before, while the production of raw silk in this country is restrained by many conditions, the manufacture of silk goods from imported raw material is going forward rapidly, and is succeeding in placing its products on the market with such traits of excellence that the foreign silks are taking a lower rank in the estimation of purchasers. Although we sincerely desire that in some way the production of the raw material may ere long demonstrate its practicability, so that our silk industry may be wholly American, it is gratifying that the manufacturing branch of the industry should be going forward, for this signifies the employment of a large number of operatives, and the money which our wealthy silk purchasers spend is going for the support of our own people rather than for the enriching of foreign nations.

An excellent compilation of facts and statistics concerning our silk industry is contained in a handsome volume, published by D. Van Ostrand, of New York city, under the auspices of the Silk Association of America, and written by W. C. Wyckoff, Secretary. The work is entitled the "Silk Goods of America," and it enters minutely into the causes and effects which mark the progress of the industry. It is but characteristic of American enterprise that the aid of improved machinery should have been already invoked, and it is true that our silk manufacturers now have fine power looms working with precision, while foreign makers are still laboring with rude hand appliances. In this country all sorts of fabrics are now made on power looms, from gossamer veiling to upholstery brocade, and goods are made with perfect uniformity of quality not attained by hand operations.

In the manufacture of silk thread, known as "sewing silk" and "machine twist," our factories have succeeded so well that foreign competition is already distanced. This branch of the industry is thriving on this coast as well as in the Eastern States. The method which our manufacturers have employed to secure a triumph for their silk thread, has been the high standard of purity which they adopted. Instead of loading the fiber with adulterants to increase its weight at the expense of strength, they determined to sell a pure, or standard dye silk. The result has been as we have said, the American-made silk thread has won the day, and those who use it not only encourage home manufacturers, but they consult their own interests by getting the better article. Foreign producers are now urged by their newspapers to adopt the American system of honesty in production, or their business will fail. This is a very significant fact. American-made sewing silks cannot be surpassed in delicacy, brilliance and permanence of hue.

One very interesting fact which is fully set forth by Mr. Wyckoff in his book, is that the raw material used by American silk makers is better than that used in Europe. He shows conclusively that American manufacturers are obliged to use the best raw silk as a simple measure of economy. The cost for labor in this country is so high that all the foreign manipulations, by which poor raw material is made to look like good when in the thread or fabric, are too expensive to practice in this country. In other words, the extra cost of the best raw silk is less than the cost of the labor required to "doctor up" the poor. Then, too, the best raw silk works well in machinery, and fabrics can be made rapidly, while the poor is continually breaking and the machinery has to be stopped to tie the ends. Thus time is lost and less work is done by the machine in the day.

In all styles of silk goods, American enterprise and machinery are winning their way. The manufacture began a few years ago with some simple lines of manufacture. It has progressed to such an extent that nearly all kinds of silk goods are produced of unrivalled excellence. It is estimated that from a fourth to a third of the plain silks and a much larger proportion of the brocade silks which are consumed in this country, are now made here. The production of figured dress silks has attained large development within a very few years. The designs are mostly original, and no mere description can do justice to the beauty and variety of these fabrics. In producing grenadines and satins, the improvements have been equally striking. Ribbons of the most elaborate design and most perfect finish are now made in this country by power looms, and they have superseded the foreign hand-made ribbons, being so superior that French makers compliment us by imitating American tickets, trademarks and designs. The finest silk laces are also made upon American machines. In short, the American silk manufacturing industry may be fairly regarded as thoroughly American in its character and methods, and highly creditable to those who are pushing it forward.

cost, depend upon it, the investment would be a good one. I weigh my words when I say that, if the nation could purchase a potential Watt or Davy or Faraday, at the cost of a hundred thousand pounds down, he would be dirt cheap at the money. It is a mere commonplace and everyday piece of knowledge that what these three men did produced untold millions of wealth in the narrowest economical sense of the word."

Barnes' Educational Monthly argues that "Technical education supposes that a child must be educated for the sphere he is expected to occupy in life. Advocates of a purely technical education use frequently such phrases as 'laboring classes,' 'station in life,' 'educated classes,' 'cultured society,' 'upper classes.' Whether this is wise in republican America as in monarchical Europe remains to be seen. Experience has shown that it is exceedingly unwise to suppose that a certain boy is to make a Congressman, while another will peg boots. The issue usually shows that the young lawmaker makes a cobbler, while the predestinated bootmaker becomes a foreign minister. Some of our very best and most learned men were not intended by their parents to occupy very high stations in life. It is dangerous to 'suppose' very much in reference to any boy in this enlightened age." Every boy and man has a genius for some particular pursuit. It should be the endeavor of educators to ascertain this genius or inclination by experimental studies and develop that one alone. We are running to specialties, and only extraordinary men can compass generalities, and even then are more in the nature of encyclopedias than profitable every-day consultants.

IN New York Government bonds are quoted at 101½ for 4s of 1907; 102½ for 5s of 1881; 104½ for 4½s; sterling, \$4.82@4.84; silver bars, 112½; silver coin, ½@ discount.

DEWEY & CO'S SCIENTIFIC PRESS Patent Agency.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system and intimate acquaintance with the subjects of inventions in our new community. All worthy inventions patented through our Agency will have the benefit of a description or an illustration and explanation in the MINING AND SCIENTIFIC PRESS or the PACIFIC RURAL PRESS. We transact every branch of Patent business, and obtain Patents in all civilized countries. The large majority of U. S. and Foreign Patents granted to inventors on the Pacific Coast have been obtained through our Agency. The files of cases and official records in our office, our patent law and scientific library (already the largest west of the Mississippi), are constantly increasing. These facilities, with the accumulation of information of special importance to our home inventors, by the experience of its proprietors in an extensive and long continued personal practice, gives them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. We can give the best and most reliable advice as to the patentability of new inventions. Advice and Circulars Free. Our prices are as low as any first-class agencies in the Eastern States.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

AN ENGINEER,

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

**MINERS' HORSE-POWER.**

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

Will find it to their advantage to call on us at 328 BUSH STREET, bet. Montgomery and Kearny, (up-stairs,) S. F.

The Mechanics' Fair.

The following are some among the most interesting exhibits in this fair:

Manufacture of Metallic Laths.

Mr. Chas. H. Carter has a machine for manufacturing metallic laths at work in this machinery department of the pavilion, both the form of the lath and the machine being of Mr. Carter's invention, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency. Metallic laths have heretofore been formed in sheets in a series of corrugated pieces, adapted for placing on broad, smooth places. The new metallic laths are made singly, and have a curved central portion with extending flanges, by means of which they may be attached to the wall. They are made in long strips, each one separate, and may be put in place like ordinary wooden laths, and weigh about as much. When placed side by side, the space formed between the raised portions of the lath produces a depression which forms the head to hold the mortar in place.

The machine for forming the laths is a simple though ingenious piece of mechanism. A sheet of metal of suitable dimensions is pushed under the plates from one side. The eccentrics, as the shaft is rotated, force the sliding plates down, thus forcing down the oppositely placed levers. These levers force down the upper edges of the swinging presser plates, the lower sharpened beveled edges of which squeeze the overlapping edges of the metal plates from which the laths are formed down over the rounded edges of the former, and into a crevice on each side. The eccentric again raises the swinging plates and separates their lower edges, releasing the lath, which may be drawn out, and a new piece of metal inserted.

The laths, thus formed singly, can be put upon any surface, and formed or bent to fit corners or angles; while they at the same time provide a perfectly fire-proof wall and a bond to hold the mortar in place. The Carter lath is now being put in the new Hall of Records in Oakland, and will no doubt come rapidly into use in all buildings designed to be fire-proof.

Bruckner's Ore Mill.

There is on exhibition, in the display of Prescott, Scott & Co., in the fair, one of Mr. Bruckner's ore pulverizing cylinders, a machine of which some 80 are in use in Europe, and which is now meeting with the favor here, which experience abroad has induced. The machine was invented some two years ago by the well-known metallurgist, Mr. Bruckner, to replace, if possible, the costly and cumbersome plant necessary for crushing by the ordinary stamp battery so much in vogue on the Pacific coast; and from the facts, which are from the experience of a considerable period, our readers can judge for themselves of its value.

It is constructed somewhat on the principle of the ordinary holt-polisher, with which every machinist is familiar. It consists in the main of a cylinder four feet long and four feet in diameter, in which a number of iron balls are placed, and which, when the machine is charged with ore, is rotated, to produce the necessary grinding. The cylinder is constructed of flat steel rails of about three and a half inches in width, placed hoop-like at distances of 3-32 of an inch apart, and securely fastened together by iron braces. The ends of the cylinder are made of strong sheet iron. The ore is charged by any continuous feeder through one of the trunnions on which the barrel turns. Around the cylinder and fastened to it is placed a cone of cast iron, so that the pulverized ore falling through the apertures between the rails is caught by the cone and carried by gravity to the part having the greatest diameter. Here is placed a hollow, annular ring, which forms a natural depository for the ore. This ring contains two cylindrical sieves. The one is made of strong punched iron or steel, and is made with 18 holes. This simply serves to protect the other, a wire screen, which is placed beneath it. This screen is usually a No. 30.

The next object is to remove this pulverized ore, which after having passed the No. 30 screen lies at the lowest part of the outermost compartment of the annular ring spoken of above. This is effected by a curved tube or channel of cast iron, which runs from the bottom of the outer compartment along the end of the cylinder to the hollow trunnion opposite that at which the ore entered the cylinder. With such an arrangement it is evident that the revolution of the cylinder will naturally discharge the pulverized ore through the hollow trunnion. By a similar arrangement all the ore which has passed the No. 18 sieve, but not the No. 30, as well as that which was too coarse for the No. 18, is taken by a similar tube and discharged back into the cylinder itself for repulverization. A little reflection will make the working plain, and it is evident that the whole operation is automatic, and that with a proper ore feeder no attention whatever is required to the apparatus. In a cylinder of the dimensions given it is usual to work with about 1,500 pounds of iron balls. The cylinder is run at a speed of from 15 to 22 revolutions per minute. A 5 to 7 horse-power engine only is needed.

Perhaps the testimony of Mr. Arnold Lohse,

a practical mill man, and chief engineer at La Barranca, Sonora, where two of these pulverizing mills have been used for two years, will show practical results better than anything. He says: "The one at the mill, which is 48x48, discharge screen No. 35, running 27 revolutions per minute, grinds 20 tons of silver ore in 24 hours. Power necessary to propel it is 7 horse-power. The one at the mine is 48 diameter by 36 length of barrel, run at 22 revolutions per minute. Discharge screen for sizing ore for concentrators are 16, 12 and 8, and grinds 30 tons in 24 hours. Six-horse power propels it easy. The repairs are not more than on batteries, and to say the least, your pulverizer is bound before long to dismiss the use of batteries in mills." The cylinder is usually run in connection with a Blake Stone-Breaker, and can be fed with anything from two to four inches in diameter. It will crush either wet or dry, and in the former case the water may be used over and over again, a great advantage in dry districts. Besides the advantages presented, there are some which have been hinted at only, and are evident from the arrangement of the machine. There is no useless work done. As soon as the ore is crushed fine enough to pass through the slits between the rails it passes out, and there is not that useless waste of energy so constant in the stamp battery. Also, this ore is not ground to that impalpable fineness which gives such a loss in the slimes of all our ordinary amalgamating contrivances. Next, the wear and tear of the parts is small. Machines of this kind, with a capacity of two tons in 24 hours, can be purchased for \$250. One with a capacity of 20 tons costs \$2,000. Mr. W. Bruckner, No. 328 Montgomery street, room 16, can furnish any further particulars if desired.

Waste Pipe Cut-Off.

In the machinery department of the fair, near the big engine, is exhibited a waste pipe cut-off and valve for water closets, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency by Levake & Grubb. This closet has a metal seat, and dispenses with an overflow, providing for valve overflow, making it a sure preventive of sewer gas entering dwellings in which the closet is placed. It also dispenses in new work with traps of all kinds, which are usually worse than useless, giving a feeling of safety which does not exist. In these closets a direct connection is always maintained between the outlet valve and waste pipe, and any leakage occurring, passes into the waste pipe and not into the bowl. When the closet is not in use the lower discharge is always connected with the waste pipe, and no overflow is necessary in the lower bowl, since, as the valve is closed, there is no connection with the upper pipe, it being tightly closed. In case the waste pipe should become stopped, all that is necessary to do is to raise the fall enough to open the inlet valve and allow the full pressure of the water to flow through the lower discharge pipe into the waste pipe, where the pressure will force the pipe clear. By this action the bowl continues closed, and no sewer gas or odor can arise, while the water may be allowed to flow as long as necessary through the waste pipe. The waste pipe cut-off and valve may be attached to basins, hoppers, or wherever a waste pipe is run. The mechanical construction of the device, though simple, is very effective in accomplishing the purpose.

Home Made Hardware.

Morris & Son, of No. 1045 Market street, make an exhibit of a few articles, all of which are of their own invention and practically introduced. Of these the pneumatic bell is prominent. The elasticity and mobility of atmospheric air fits it for becoming, under suitable appliances, the most perfect medium known for sending signals and ringing a bell. Morris' bell is rung by means of pressing air by a common bell pull through a small metal pipe or tube leading to the bell. It does away with all wires. For steamboats it is particularly useful, since in the case of wires breaking frequent accidents occur. They show a steamboat bell with a detector attached. This consists of a small bell in the pilot house, which rings when the engineer's bell does, but when the latter fails to ring the detector does not, so the captain or pilot will know it immediately. The pneumatic bell is in use in the Board rooms of the S. F. stock board, having displaced an electric bell. The Morris door knob, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, as was the bell also, is exhibited. This door knob is adjustable without any screws or washers, and fits any thickness of door readily, by a very ingenious and simple construction. It has been adopted in the new city hall, and is rapidly coming into use. The firm also show an improved lock invented by them and of home manufacture. It is a five-tumbler lock, very light and strong. It is adapted for prison locks, as well as for general use where care is to be exercised. Morris & Son also manufacture locks and hinges, bronze work, nickel-plated goods, as well as bells, knobs, etc.

WM. HAWKINS, of 210 Beale St., exhibits in running order his improved elevator hoist, patented through the MINING AND SCIENTIFIC PRESS Patent Agency not long since. The only gold medal awarded at the fair last year was given for this machine. A long revolving screw carries the cross-head to which the hoisting ropes are attached, thus hoisting the elevator steadily and easily, without any jerk or jar.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS TO DEWEY & CO.'S MINING AND SCIENTIFIC PRESS PATENT AGENCY.]

FOR THE WEEK ENDING AUGUST 26TH, 1879.

- 218,930—CAR COUPLING—C. Chisholm, Los Angeles, Cal.
 218,933—HORSE POWER—H. M. Cox, Linden, Cal.
 218,975—CULTIVATOR, HARROW AND SEED-SOWER—James Hugill, Woodbridge, Cal.
 218,977—WINDMILL—M. C. Jackson, Alvin, Cal.
 218,992—PEACH AND PLUM PITTER—J. Lyon, Placerville, Cal.
 218,995—COMBINED BOOT AND LEGGING—P. McNulty, S. F.
 219,018—BLACKING-BOX HOLDERS—L. F. Reichling, Oakland, Cal.
 219,028—RAILWAY TRACK LUBRICATOR—F. P. Smyth, Cuffey's Cove, Cal.
 219,018—ELECTRIC AMALGAMATOR—J. O. Stewart, Alameda, Cal.
 219,050—MINE DRAINING APPARATUS—J. R. Wilcox, S. F.
 7,628—CIGARS—Trademark—M. P. Kollberg & Co., S. F.
 7,629—CANDLES—Trademark—Lavenson, Winter & Co., S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

IMPROVED CULTIVATOR, HARROW AND SEED-SOWER.—James Hugill, Woodbridge, San Joaquin county, Cal. Patent No. 218,975. Dated Aug. 26th, 1879. This invention relates to an improved farming implement, by which the ground is harrowed, cultivated and seeded at one operation, thereby saving a great deal of time and expense for farmers. The construction of this machine is simple and not liable to be easily broken; it consists of two large rollers arranged to operate independently of each other, rotating freely upon an axle which is journaled in a frame; on the outside of these rollers are placed in diagonal lines a series of teeth. Behind these two larger rollers is a small one having teeth arranged so as to keep the teeth on the large rollers free from lumps, and is connected to the larger rollers by means of a set of gears. Near the rear end of the frame is arranged a seed-trough in which the seed is placed and dropped as required, and afterwards covered by means of teeth secured in the rear beam of the frame.

AUTOMATIC MINE-DRAINING APPARATUS.—Joseph R. Wilcox, S. F. Patent No. 219,050. Dated, Aug. 26th, 1879. This invention relates to an improved apparatus for raising water from mines, wells, etc., and consists in providing two sets of three cylinders each, one set inside the mine and the other set outside, the latter being placed at a lower point than the inside set. Each set of cylinders is placed in line, so that one piston-rod may carry three pistons, one for each cylinder. Two pipes connect with opposite ends of each of the central cylinders, so that a continuous pipe leads from one end of the inside central cylinder up and down into the mine, connecting with the outer end of said inside cylinder, thus forming a continuous double water column when said pipes are filled and sealed.

HORSE-POWER FOR OPERATING PUMPS.—Henry M. Cox, Linden, San Joaquin county, Cal. No. 218,938. Dated Aug. 26th, 1879. This device consists in the employment of a bevel or crown wheel, which is fixed upon a bed with its teeth uppermost. A central spindle arises from this wheel, and an arm or lever mounted upon this spindle extends across above the gear wheel, having an attachment for the horse at one end, while a pinion at the other is mounted to rotate upon its axis by meshing with the teeth of the large wheel while the lever is carried around by the movement of the horse. A crank-arm upon the pinion is united by a pitman and universal joint with a balance-beam above, and the action of the crank causes it to oscillate so as to operate a pump at the opposite end. This device is simple and easily constructed.

COMBINED BOOT AND LEGGING.—P. McNulty, S. F. No. 218,995. Dated Aug. 26th, 1879. The object of this invention is to provide a combined boot and legging adapted to fit over the pantaloons and fit the ankle and leg symmetrically; and it consists in a boot having one side of the leg narrow and the other side projected toward the front to a sufficient width to wrap over the front of the leg onto the other side of the boot leg, the sides being provided with fastening devices, and connected at the front with gore of thinner material, and lapping over when the leg-flap is secured.

RAILWAY-TRACK LUBRICATORS.—T. P. Smyth, Cuffey's Cove, Mendocino Co., Cal. No. 219,028. Dated Aug. 26th, 1879. This device relates to a novel method for preventing the retarding friction which usually occurs between the moving trains upon railways and the rails where curves exist; and it consists in the appli-

cation of water to the rails and wheels in such a manner as to prevent in a great measure this retarding friction, while at the same time allowing sufficient direct adhesion for the purpose of traction.

News in Brief.

ROBERT BONNER is now the owner of "Rarus." Affairs in Hayti continue in a troubled condition.

THE had state of affairs continues at Constantinople.

THE British resident at Mandalay has been withdrawn.

THE Chilean Minister of War has tendered his resignation.

A TERRIFIC hail-storm occurred Friday at Fort Keogh.

DURING August 2,787,059 standard silver dollars were coined.

THE excess of exports over imports during 1879 is \$263,572,089.

ANOTHER party of farmers left Liverpool last Saturday for America.

THE public debt statement shows a decrease in August of \$527,395.

A BROTHER of the Pope died at Rome, September 2d, of apoplexy.

THE Austrian budget this year shows a deficit of 21,000,000 florins.

"MOLLIE McCARTY" is broken down and will probably never run again.

SPECIE in the Bank of France decreased 1,527,000 francs the past week.

THE coal miners of the Cumberland region in Pennsylvania, are on a strike.

DON CARLOS denies that he has compromised his claims to the throne of Spain.

EX-QUEEN ISABELLA will attend the wedding of Alfonso and Archduchess Marie.

WHOLESALE arrests were made at Houston, Tex., for violating the quarantine laws.

SILVER in London, 51½d; consols, 97 11-16; 5% U. S. bonds, 105½; 4s, 104½; 4½s, 108½.

THE state of siege in the recently disturbed districts of Bulgaria will shortly be raised.

THE interest at the East in regard to the De Young-Kaloch business has about died out.

THE deaths at Memphis from yellow fever to date number 233—163 white and 50 colored.

IN Staffordshire, England, 50,000 workmen are affected by the recent reduction in wages.

THE death of John Adams Jackson, the American sculptor, is announced from Florence.

A LETTER from Tangier announces the death of a brother of the Emperor of Morocco by poison.

GEN. TODLEBEN, Governor General of Odessa, is to be relieved by Prince Don Dankoff Korsakoff.

A RAILROAD is soon to be built from Austin, Nev., to the Central Pacific, a distance of 90 miles.

THE Oneida community has been compelled by public sentiment to abandon its free love system.

AT Liverpool wheat is quoted at 8s 6d@9s 6d for average California white, and 9s 5d@9s 10d for club.

SINCE August 12th \$4,000,000 in gold has been received at the New York assay office from London.

ENGLISHMEN at Constantinople strongly protested against the proposed new taxes on foreigners in Turkey.

STEAMERS leaving Europe during the last three days for New York have on board \$5,500,000 in gold.

TROUBLE is reported in the States of Coahuila, Durango and Chihuahua, Mexico, over disputed mining ground.

THE number of gallons of spirits produced during the fiscal year 1879, is 71,892,617, against 56,103,053 in 1878.

THE President will enforce his order in regard to the active interference of Federal officials in political conventions.

THE coinage at the Philadelphia mint during August amounted to \$2,233,497, of which \$1,876,050 was in silver.

THE programme of the prize shooting at Creedmoor contemplates 19 matches, with an aggregate value of \$7,277.

ALL the gambling houses in St. Louis are to be closed after Sunday night, under the new law, which is very strict.

GENERAL GRANT does not desire to be President again, according to a letter from him to the Hon. Elihu B. Washburne.

RICHARD STEVENSON, United States Deputy Marshal, was shot to death last Saturday by a horse-thief, near Wellington, Ka.

A MONSTER meeting was recently held at Tirnova to protest against the unconstitutional acts of the Bulgarian government.

THE Italian military maneuvers were abandoned because it was not thought advisable to concentrate troops near the Austrian frontier.

WOODEN RAILWAY.—The *Engineering News* says that a wooden railway is in practical operation at Live Oak, in Florida. Pine or other logs are split in halves and laid on the road bed with the flat side up for a track. Dove-tail the ends together, make the top surface smooth, the sand will pack under the logs and hold them in place, lay the logs far enough apart for a mule to travel between, and the track is completed. The car is kept to the track by making the wheels eighteen inches or two feet wide. It is found that eighteen inches width of wheel gives play enough, so that it is impossible for the cars to leave the track.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Gila, Aug. 30th, \$5,000; Northern Belle, Aug. 30th, \$4,666.71; Martin White, Aug. 31st, \$7,284.16; Bodie Con., Sept. 1st, \$17,000; Christy, Sept. 2d, \$8,193; Hillside, Sept. 2d, \$4,200; Hillside, Aug. 23th, \$4,200; Northern Belle, Aug. 25th, \$2,978.96; Alexander, Aug. 23th, \$5,133.64; Ophir, Aug. 27th, \$24,394.12; Hillside, Aug. 30th, \$4,100; Martin White, Aug. 27th, \$5,357.15.

TENACITY OF PURPOSE.—The life of Louis Favre, the well-known Swiss engineer, and the constructor of the St. Gothard tunnel, furnishes an example of tenacity of purpose worthy of imitation. When he began the building of the tunnel, which he was not permitted to see completed, he was attacked in the wildest manner by engineers and mechanics, who accused him of being a dreamer and a man devoted to idle theories. He was a genius, however, and forced his way from a poor lad to a world-wide reputation as a practical theorist. He died worth millions, which is not so much to the point of the moral involved in his life as his steady perseverance against obstacles to the carrying out of well-grounded theories.

LABOR.—The world owes most of its growth to men who tried to do as much work as they could. The debt is small to those men who worked as little as possible, and there will not be many credits to those who shirk. To most men more than eight hours work is necessary for the maintenance of physical, mental and moral health. The forces of the animal nature and passions can only be kept down by physical exertions. If mechanical improvements should discharge men from the necessity of laboring more than six hours a day, there is no doubt that society would rot in measureless and fatal animalism.

A Library for Inventors.

We have at our patent offices, No. 202 Sansome street corner Pine, a complete set of Patent Office reports, containing engravings and claims of every patent ever issued in the United States.

We have also a complete set of the MONTHLY VOLUMES issued by the Department, with full detailed description and large drawings of all the patents issued since the time when these volumes were first published.

A set of all the LAW BOOKS ON PATENTS is also on our shelves ready for reference. We have also the British Commissioners reports, Canadian Patent Office reports for all British North America, full files of MINING AND SCIENTIFIC PRESS, PACIFIC RURAL PRESS, Scientific American, Scientific American supplement, American Artisan and other American and foreign scientific and mechanical journals, as well as mechanical dictionaries, chemistries, encyclopedias, and other works of reference.

Inventors and patentees are WELCOME TO EXAMINE at their leisure any of the books in the above sets, and we shall be glad to give them any assistance in hunting up what they want.

Our library is the most complete of its kind on the Pacific Coast in every respect, and we are continually adding to it as occasion demands. DEWEY & CO.,

Patent Agents and Publishers,
No. 202 Sansome street, corner Pine, San Francisco

Back Numbers Wanted.

The following volumes and single copies of the MINING AND SCIENTIFIC PRESS are wanted at this office, for which a reasonable price is offered:

Year.	Volume.	Number.	Description.
1870	20	2	Complete volumes, 1st half (of year).
1870	20	2	Copies of No. 2, Jan. 1st.
1870	20	1	Copy each of No. 1, Jan. 1st, 3 of Jan. 14th, 7 Feb. 11th, 6 Feb. 4th.
1870	21	1	Copy of No. 7, August 13th.
1871	22	5	Copies of No. 1, Jan. 7th.
1871	22	3	Copies of No. 5, Feb. 4th.
1871	22	1	Copy of No. 3, Jan. 21st, 6 of Feb. 2d, and 1 of May 1st.
1871	23	1	Copy of No. 2, July 15th, and 9 Sept. 2d.
1872	24	2	Copies of No. 4, Jan. 27th.
1872	24	3	Copies of No. 7, Feb. 17th.
1872	24	2	Copies of No. 17, April 27th.
1872	25	1	Copy of No. 10.
1872	25	1	Complete volume, last half (of year).
1873	26	3	Copies of No. 8, Feb. 22d.
1873	26	3	Copies of No. 9, March 1st.
1873	26	2	Copies of No. 10, March 8th.
1873	26	1	Copy of No. 7, Feb. 15th.
1873	27	3	Copies of No. 20, Nov. 15th.
1873	27	4	Copies of No. 21, Nov. 22d.
1873	27	3	Copies of No. 24, Dec. 13th.
1876	30	1	Copy of No. 4, Jan. 22d.
1875	30	1	Copy of No. 5, Jan. 30th.
1875	30	1	Copy of No. 8, Feb. 20th.

HELP IN ACQUIRING KNOWLEDGE.—In acquiring a knowledge of the English language, and especially in learning the meaning of words, probably no other work, nor many other books altogether, can afford so much aid as Webster's Unabridged Dictionary, with its 3,000 pictorial illustrations, its precise and full definitions, its careful discrimination of synonymous words, its many valuable tables, and above all with the recent additions to it of an supplement of over 4,600 new words and meanings, such as have come into the language within the last few years, and a new biographical table of more than 9,700 names of noted persons, giving in brief the name, pronunciation, nationality, profession and date of each. It is, in itself, a whole library of the language. Let one family have a copy of this work, and use it faithfully, and another be without it, the difference in the progress of the two families in getting knowledge will be very great.

Fresh attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

HOW TO STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

Designing

and

Engraving

at

This Office.

We are prepared to do fine Wood Engraving for illustrating Landscape Scenery, Buildings, Machinery, Works of Art, Manufactured Articles, Trade Marks, Seals, etc. We have a first-class

Machine for Engraving

A portion of the work, which can be finished thereby more perfectly than by the eye and hand alone. Our patrons can depend upon first-class work always, and at reasonable prices. Samples can be seen at our office.

DEWEY & CO.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quick-silver, 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore of each. It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ore generally, with 120 Lithographic Diagrams, 1877. This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

SITUATION WANTED.

A competent Assayer, who has had some experience in Mill Work, desires a position with a Milling or Mining Company. The best of references. Apply to

JOHN TAYLOR & CO.,

512 Washington St., San Francisco.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Mining Machinery Depot,

PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Small Sizes made in Sections not to Exceed 300 lbs.

Patented June 25th, 1878.

RUSSELL'S AMALGAMATOR.

SAVE YOUR GOLD And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated. With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

Lathe Without Saw Attachments.

Material eighteen inches long and eight inches in diameter can be turned upon it. The pieces that accompany this Lathe without extra charge are two T rests, two planers, one spur center for wood turning, and one face plate.

This lathe has been made especially to meet a want felt by many for a really good and substantially made Lathe. It is by far the best Lathe ever placed on the market at the price asked. The headstock is made of iron; the spindles of steel. The bearing of the head stock is conical, so that the wear can be easily taken up.

Price of Lathe without Saw Attachments, \$45. Price of Lathe with Scroll Saw Attachment, \$55. Price of Lathe with both Scroll and Circular Saws, \$70.

Trump Drill Chuck.

Chuck for drills $\frac{1}{4}$ and under, Price, \$1.50
Chuck, for drills $\frac{1}{2}$ and under, Price, \$2.25
They are made on solid steel plug, centered and readily fitted to Lathe or Drill Press.

TO QUARTZ MINE OWNERS.

Parties having, in California, where water can be had for
power, a quartz lode, carrying pay ore, and sufficiently de-
veloped to warrant the erection of machinery, and are willing
to give one-half of their property for such works as the mine
will justify, may be benefited by addressing the undersigned.
State locality of mine, size, lay, course, development, forma-
tion, surroundings, wood, water and such other particulars as
will show value. Address

GIANT POWDER

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive.

Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. Triple Force Caps and all Grades of Fuse.

BANDMANN, NIELSEN & CO.,

SAN FRANCISCO, CAL.

THE POOR MAN'S PROSPECTING HAND OR POWER QUARTZ STAMP MILL.

Two men can operate it all day. It is simple, efficient and durable. The force of the blow can be changed so as to strike a light or a very heavy blow readily. Two men can work this Mill to its full capacity, and do this work as well as can be done with any of the old-style heavy Stamp Mills. An inspection of this Machine will convince any practical person that it is the most perfect QUARTZ STAMP MILL ever produced in this or any other country. A large number of old practical Miners have seen it, and they all say it is a perfect Hand Stamp Mill. We put on a band pulley, so it can be run with power. This cut is a correct representation of C. EATON'S Patent LATELY PERFECTED MILL

— FOR —

PROSPECTING
IT IS SIMPLY
Perfection!

When power is used each Stamp will strike 150 blows per minute. The force of the blow in comparison to the face of the Stamp ($4\frac{1}{2}$ inches) is greater than that of any of the heavy power Stamps. Stamps and Dies cast on Chill. These Machines are well and thoroughly made, nothing about them to get out of order. They are put together with bolts. Can be taken apart readily, so as to be convenient to pack on a mule's back. The whole machine weighs about 1,300 pounds. The heaviest piece weighs 200 lbs. These Mills will do more work (according to money invested) than any of the old heavy Stamp Mills. For sale at AMES' STEAM ENGINE DEPOT, 14 S. Canal street, Chicago, Illinois. Net Cash Price, \$150.

THE IMPROVED

PARKER SHOT GUN.

For Close, Hard Shooting, the
Parker Cannot be Excelled.
Send stamp for new Catalogue.

MUZZLE and BREECH-LOADING SHOT-GUNS and RIFLES and AMMUNITION.

The new Burgess Repeating Rifles—45 cal., 70 grains; Whitney and Phenix Rifles, Muskets and Carbines; Phenix Single-Barrel Breech-Loading Shot Gun; Allen Rifles, 22, 32, 38 and 44 caliber, rim fire, very cheap; Lovell & Sons Revolvers, the best and the cheapest.

Twenty-Nine Years a State.

On the evening of September 9th last, the 29th anniversary of the admission of California to the Union, was celebrated with appropriate ceremonies by the Territorial Pioneers, at the Bnai Brith hall, Eddy street, San Francisco.

There is very little in this mere announcement of this anniversary to distinguish it from any other anniversary, unless we recall to our mind's eye the progressive development of California from her admission to the Union to the present times; her condition and prospects then, and her prominent position in the world now. There are men now living, and they are comparatively young, who came to our shores when the whole of the Pacific slope was either so thickly settled as to be a comparative wilderness, or contained a different race of men than those who now throng its hills and valleys.

Long ago, before our rich mineral and agricultural resources were known to the world, a writer in drawing conclusions from the early history of mankind, predicted that the greatest civilizations and power of the vast territory of the United States would, in some future period, be found in the narrow strip of country west of the Rocky mountains. The prediction now seems like an inspired prophecy, and near its fulfillment.

In the year 1848 there was nothing in the "signs" which pointed to California either as an El Dorado, or as an empire within an empire. On the 19th of January, 1848, James W. W. Marshall, picked up in the race of a mill, on the banks of the American river, a piece of bright, yellow metal. He was ignorant of its nature. Mrs. Elizabeth James Wimmer, who lived in the vicinity, pronounced it gold, from her knowledge of that metal while living at the gold mines of Georgia. That was all. From this simple find was to arise the greatest civilization of the vast territory of the American continent. From all parts of the world came a vast motley crowd. Where were the mines of gold and silver of other parts of the world that up to this time had been so well and so favorably known? They were still yielding, as they are now, and as they will, perhaps, to the end of time, a constant supply of the world's medium of exchange. The world took cognizance of the magnitude of California as an El Dorado, as if it had received a revelation. The world's supply of gold and silver was inadequate to the needs of increasing commerce. Governments were endeavoring to solve the problem of how to increase the money supply, to prevent the languishing of what was foreseen to become gigantic international commercial relations. Statesmen had in vain pondered over the matter and recommended measures, but in vain. The small, bright, yellow piece of metal found on the American river at Sutter's mill solved the problem; introduced a new philosophy; a new system of political economy among nations. From that time to this, only 30 years, hardly one generation, untold millions have been yielded up from the treasure stores of our State, and an empire has its foundation laid in the solid rock of prosperity. The grand achievements resulting from this shining yellow piece of metal are not confined to our own State. They spread over the whole world and have brought about a civilizing influence. A cosmopolitan, international spirit has pervaded the entire mass of humanity upon the earth, and the world has progressed. Would it have been as far advanced if California were still unknown? We are bold enough to utter an emphatic denial. Our wealth is yet untold. The surface of the ground has alone been imperfectly touched by the pick of the miner. The refuse of early days is now yielding wealth to more careful hands. Our veins of gold and silver are exhaustless, for nature is not eccentric in the deposit of her riches. She has placed her most precious minerals within our borders, and to find one line of mineral is to find promise of another. Gold and silver mining is as old as the first gathering of the human race into nations. No history refers to an epoch anterior to the use or search of the precious metals. Their discovery, obtaining and use, have exerted a refining influence, and those nations engaged in their production and circulation were proportionately

progressive in wealth, power and arts. Where are the signs of decay in our mines? Only 30 years in all and but few of those 30 years spent upon veins, nearly all upon placer mining. Centuries have not exhausted known and well-defined metalliferous veins, they are productive as long as power can be provided for their working. Such has been the experience in Europe, and greater than that will be the experience of California, inasmuch as her golden veins are richer and more numerous. The scepter of power and civilization has been within our grasp but a short time only, for our State is but an infant in age, though of strong promise, but a future generation looking down from its advanced position, will still feel all the wonder at 60 years of growth, as we now feel at only 30. Our mines are waiting the fruition of the prophecy alluded to in the beginning.

New Zealand Gold Fields.

It appears from the last number of the *Thames Advertiser*, that the output of the gold mines of New Zealand from the 21st of July to the 15th of August was about 2,000 tons of ore, which yielded under the stamps 2,697 ounces, and 8 dwts. of gold, equivalent to an average of about 1 1/3 ounces per ton. This yield is regarded as very satisfactory. The Borough Council has consented to contribute 250 per month out of the gold duty toward paying this big pump. The County Council declined to

DERICKSON'S TEN FOOT EXTENSION RULE.

consider an application for a like amount. This pump, however, is again in operation, and had, during the week previous to Aug. 15th, reduced the water in the mines 40 feet.

To save expenses the engineers stoke for themselves, and keep only a pitman and a lad to wheel coals and run messages. Six of the miners have quartz lying stacked outside the drive, which they are unable to have hauled to the crushing mills on account of impassable roads. The accumulation of quartz has been so great that it interferes with the output, which is consequently less than it would be if facilities for removing it existed.

In the Moanatairi mine a large quantity of paying stone is being taken out. The ledge at the 150 level is 18 inches thick, and of promising appearance. The rock drill is working satisfactorily, being more expeditious and cheaper than by hand. There are fine gold-bearing stringers in the face of the drive.

In the Tairua district considerable prospecting is going on, and in one claim there have been found two crevices of quartz, about a foot thick. Gold has shown itself all the way down to 60 feet, the depth sunk, but the richer stuff was obtained nearer the surface. A parcel of about 30 tons, recently taken from it, gave a return of 45 ounces of gold.

The drainage question is regarded as very important in the mining region, and the Drainage Association have secured the co-operation of all the mines in their efforts to keep them free of water. The most auriferous portions of the mines are under water and cannot be worked. New machinery, including a turbine, are being put in, however, which it is hoped will accomplish the object of their desires.

The new Cassiar Mining district of British Columbia has been abandoned, the claims being worked out.

City Foundry Notes.

Fulton Iron Works.

The Fulton Iron Works (Hinckley, Spiers & Hayes) is one of the only two large foundries which are at present doing very much work in this city, business in this line being very slack as a general thing. Among other work under way at the Fulton is a 30-stamp mill for the Noonday mine at Bodie. This order also includes 24 five and a half-foot pans, 12 eight-foot settlers, a 23x48-inch engine, and three steel boilers, 54x16 inches, the whole forming a complete outfit for this mine. They are also building a 20-stamp mill for the Western Mining Company, Tombstone district, Arizona, together with 14 five-foot pans, 7 eight-foot settlers, an 18x14 engine, and two steel (54x16) boilers. This order includes all the necessary shafting, pulleys, retorts, etc., etc., for the mill.

Among other work just completed is a 10-stamp mill for the Paradise mine, Nevada, with a 16x36 engine, four pans, two settlers, and a 55x16 boiler. Another 10-stamp mill has been shipped to the Monumental Mining Company, Oregon. The whole mill was complete, and included four pans, two settlers, a 14x30-inch engine, two 42x16 boilers, etc. They are also building a hoisting engine for the McMillan mine, Globe district, Arizona, with engines, boilers, etc., complete. Are building a 16-inch pump, 10 feet strokes for the Enterprise mine, Plumas county, Cal. They are doing the usual

amount of small work, some steamboat repairing, etc. The Fulton has been pretty busy all summer, and is now working full handed with 170 men.

The Risdon Iron Works.

The Risdon Iron Works are at present making a number of mining hoisting engines of the compound type, a form which meets with much favor. They are made with 9 and 18-inch cylinders, and are compact and in one piece. They work from 1,200 to 1,800 feet with great success. Mr. Moore, the superintendent, informs us that in Europe they are now compounding all the locomotives, as they did many steamers here when this form of engine came more into favor. We are not advised as to details of the method of compounding the locomotives, but it has evidently been successfully accomplished.

FOREIGN MINERS NOT WANTED.—A correspondent of the New York *Sun*, under the above caption, regards the agitation in favor of the immigration of English miners to the coal fields of Pennsylvania as nothing less than criminal, because there is no demand for miners and laborers in the anthracite region of Pennsylvania. The present force of miners and laborers number about 70,000 men and boys, and they can mine the regulation 22,000,000 tons per year by working only three days a week. We do not apprehend that all foreign emigration of miners is directed to the coal-fields of Pennsylvania, nor are the jealousies and disturbances in that region destined to rend the country asunder. We happen to have rich mines on this coast, and welcome intelligent labor with capital. The continuation in the East of a close corporation spirit will perpetuate the Pacific slope.

A Ten-Foot Extension Rule.

William J. Derickson, of Clayton, Contra Costa county, has recently patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, a very convenient tool for carpenters, bridge builders, and all mechanics who use a ten-foot pole. It is simply a ten-foot extension rule, properly graduated, and made in four pieces.

Figure 1 shows the first two parts of this rule, connected by the slides, E and F, which allow of the parts sliding by each other. When a desired measurement is reached the parts are secured by means of a set screw, on the slide, E, when the measurement may be read on the face of the slide, E. Some of the rules are made with a cam, instead of a set screw, an arrangement somewhat more convenient, as more quickly connecting or disconnecting the parts.

Figure 2 shows the ends and connections of the ten-foot extension. The left shows the joint, connected and held in place by means of the spring, m, entering the slot, n, from the inside, which is relieved by pressure when the joint is withdrawn. The right shows the joint withdrawn.

Outside measurement may be taken by means of the callipers, J J, Fig. 2; and there are similar callipers in the five feet extensions. The calliper measurements are read on the narrow edges of the rule, and indicated by the point on the sides of the slide, E, Fig. 1, which accounts for the space taken up by the callipers. Figure 3 shows the compact form of the rule when placed in a chest, 1 foot 8 inches by 1 1/4 by 1 1/4 inches.

This rule will describe circles or curves of any desired radius of 10 feet or less, by the use of the trammels, D D, Fig. 1. A common pencil may be screwed in the place of either point, if desired. The points being parallel with the clamps, they may be placed flush at the ends, using this extension to measure; or, they may be used on one of the pieces, by moving one of the clamps to the measurement desired.

The callipers, on plates J J, are provided with springs on their spindles, so they will be kept down flush when closed, and may be raised by the thumb in taking outside measurements.

To measure circles, or arcs of circles, the trammel clamps are put in place on the ends. The parts are adjusted by each other until the proper size is reached, when one point is placed down, and the other describes the arc or circle of the required size. The trammels may be put on the ends of the short pieces, A A, or may be slid up or down either of the parts to suit requirements.

The ordinary ten-foot rules used by carpenters, bricklayers, and other workmen, are very troublesome from their inconvenient size. New ones have to be made very frequently, and the fractions of feet have to be measured with the two-foot rule, they not being marked on the poles. Two rules have, therefore, to be used to get one measurement.

Then again, two pieces are lapped upon each other and nailed together, and then measured, for taking inside measurements. Mr. Derickson's device overcomes these obstacles by making the rule in the four parts which slide by each other as described; and whenever a measurement is taken, either inside or outside, the dimensions are marked on the scale accurately in feet, inches and fractions of inches, as shown. The whole rule may, when closed, be placed in the chest with the ordinary tools. The rule is now on exhibition in the Mechanics' fair, division W, on the partition of the stairs leading to the gallery from the Market-street end of the machinery department.

BODIE BULLION YIELD.—The bullion yield of Bodie district for the month of August amounted to \$213,518.15. Of this amount the Standard shipped \$138,039.68; Bodie, \$69,567.40; Noonday, \$5,911.07. For the months from January to August inclusive the production of this camp footed up a grand total of \$1,563,066.85. For the same period of 1878 the shipments amounted to \$1,308,959.68. It will be seen that the output of bullion so far this year has been greatly increased over that of 1878. The increase amounts to \$251,107.17. The Standard has shipped two bars this month, amounting to \$35,181.17.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents. — EDS

Poisoned Water.

EDITORS PRESS:—Much has been said and written in regard to the poisoning of water by the use of lead pipe. It is now asserted in some quarters that galvanized iron pipe, now extensively used in place of lead, is equally poisonous, or more so; also that the brass (or other composition) rods used in force pumps are open to the same objection.

It is also asserted, by physicians and others, that the water from the elevated tanks in common use throughout the country is poisonous and unfit for drinking. As these are matters of great importance, not only to individuals and families, but to the whole community, please enlighten us in regard thereto, chemically or otherwise; and also state in what the process of galvanizing iron consists, and what is the best pipe for the conduct of drinking water. — DUNK WATER.

EDITORS PRESS:—It would be easy to write a volume in giving a full reply to the above inquiry, the subject being one whose importance is only equalled by the difficulty of giving rules applicable to all cases, and avoiding the jumping to hasty conclusions.

First, as regards the use of zinc, whether in independent sheets or covering the surface of sheet-iron ("galvanized"), I have for many years past warned and protested against the tendency to its use in place of tinned iron (tin-sheet) for almost all purposes. We have seen "galvanized" tanks and evaporators for acid juices; ditto preserve kettles, milk-pans, and finally, even churn-dashers, warmly recommended as cheap and innocent substitutes for tinned sheet, copper and brass, as well as for iron, and even wood. I claim some merit in disposing of the zinc churn-dasher, by publishing an analysis of some of the resulting buttermilk, which was thick with the zinc compounds formed in its corrosion by the sour cream; but then, it made the butter (and such butter!) come in the twinkling of an eye. However, I still see the "galvanized" preserve-kettles and cooking-pots for sale in the shop windows, and often feel curious how the consumers of their contents stand it.

It is not altogether easy to explain to the unprofessional reader just when and where zinc, or zinc-covered iron, must not be used in connection with substances designed for eating and drinking. As for copper and brass, they may be considered unobjectionable for water pumps and for vessels used in ordinary culinary operations, provided the latter are kept perfectly bright and acid or salty messes are not allowed stand (or in the case of fruit even to cool) in them, especially when exposed to the air. It is at the edge of the fluid, where it meets both the metal and the air at the same time, that corrosion of these metals occurs; hence there is little danger in boilers kept close, and none at all in the case of copper bottoms to kettles, etc., unless they are allowed to stand dirty when empty; when they must be scoured bright before using again. The fact, however, that the safety of the family depends so much on the cook's cleanliness, has caused copper kitchen pots to be largely discarded in favor of tinned sheet iron; both because tin "rusts" but very slowly, and when it does so the product is hardly to be classed as a poison. Yet when acid fruits, for instance, stand in open tin vessels for a length of time, tin will be dissolved and manifests itself in a change of color, progressing from the margin inward.

It is quite otherwise with zinc surfaces. Zinc dissolves readily in any acid, or even saline liquid, in the absence as well as in presence of air; and boiling, which in the case of copper diminishes the action, on the contrary greatly accelerates the solution of zinc. Any one making currant jelly in a zinc or "galvanized" preserve-kettle, must have noticed the froth that quickly gathers around the edges, and continues to rise while the juice is in the vessel, accompanied by a peculiar odor like that of impure hydrogen gas. Of course the operation leaves the kettle beautifully bright, for the dissolution of the metal goes on steadily so long as it lasts. As all fruits, vegetables, meats, etc., are more or less acid, and as salt water exerts a similar action, it is clear that the use of "galvanized" cooking utensils involves a steady consumption of zinc on the part of the family.

It has been contended by some that zinc is so bland and genial a metal, that the small amount thus conveyed into humanity may be viewed in the light of the administration of a gentle tonic like iron. Homeopathic believers would, however, consider it a pretty heavy dose; and few but interested persons will recommend to the general public the habitual administration of even small doses of any medicine whatsoever. The alleged blandness, however, is but illy illustrated in the most common compound—white vitriol or zinc sulphate—which not unfrequently gives rise to severe cases of poisoning, being easily mistaken for epsom salt. When it is considered that the habitual taking of such small doses of even the latter as are contained in the water of some regions, is sufficient to affect the health of the population most seriously, we must conclude that the use of zinc or "galvanized" vessels for kitchen, dairy or any similar purposes, involving the use of acid or saline fluids, is absolutely and unqualifiedly unsafe, and the lead frequently contained in it renders it doubly so.

The fact that some of its compounds are given medicinally in doses as large as those of iron compounds, lacks cogency in that the soluble iron salts (for example, coppers) have such an intensely disagreeable taste that no one will

consume them unperceived. As is well known to housekeepers who have tried to stew or preserve fruit, etc., in iron vessels, and have seen the mess assume the color and taste of ink, no such safeguard exists in the case of zinc salts; the metal is more readily corroded than iron, and large quantities may pass unperceived into the system.

The case is not so clear, however, in regard to cold water pipes and tanks. The action of pure water on zinc surfaces is very slight, even in the presence of air; but the ordinary drinking waters are far from pure, and, at the same time, the kind of impurities they contain is exceedingly various, and these are very diverse in their action upon zinc. I think it may be said in general that good drinking water, especially that from streams, may, without danger to health, be passed through "galvanized" service pipes. Unfortunately, a good deal of the water actually used would not come under the above head; and, such as is naturally objectionable, whether on account of the presence of decaying substances or of mineral salts, is precisely that which also exerts a strong influence on the zinc surfaces of pipes and tanks.

The use of bare zinc surfaces in tanks is much more objectionable than in pipes, because of the free access of air and of the decaying matter that will accumulate and ferment there. Some waters will eat through an ordinary zinc sheet near the water surface of a tank in the course of a year; and the zinc so removed will, of course, have been swallowed by the consumers. There can scarcely be an excuse for not disposing of all trouble, expense and danger in this case, by giving the tank a good inside coat of asphaltum, paint or varnish, in every case. It is proper to say, that, from experiments made with sea water, it appears that "galvanized" sheet is much less acted upon by saline liquids than simple sheet zinc.

As for the water in the common elevated wooden tanks of the country, it is hard to say anything that would be absolutely true of all. The larger the tank, or rather the more slowly the water passes through it, the more liable it is to become foul; and, in general, all water from large tanks ought to be filtered through a charcoal filter before using it for drinking. This simple process disposes not only of all decaying matter, but also, in a great measure, of whatever metallic impurities may have been introduced by the pipes or pumps. Such filters are so simple and cheap, and so readily kept in order, that wherever there is any possible danger of water contamination, they ought to be used continually; as is actually done in many parts of the United States. And most users will be both surprised and edified when, at the semi-annual or annual cleaning out of the filter, they contemplate the array of filth, including bugs, maggots and nastiness of all kinds, from the virtual consumption of which this simple device has preserved them.

E. W. HILGARD.

University of California, Sept. 2d, 1879.

Utah.—Little Cottonwood.

EDITORS PRESS:—I have just had my attention called to an interview of the editor of the Salt Lake Tribune with Prof. J. S. Newberry, of Columbia College, on the subject of the prospects of different mining districts in this State.

Concerning this Little Cottonwood district he is reported to have used the following language:

"Little Cottonwood, which includes the famous Emma, Flagstaff and other noted mines was the next district visited by me. The nature of the mineral deposits here is totally different from those in Parley's Park. In the Park they are true fissure veins which carry comparatively little galena, and the ore is to be treated by milling rather than by smelting. In the Cottonwood, on the contrary, the ore occurs in chambers in limestone, was originally mainly galena, but is now changed to carbonate of lead. The nature of these mineral deposits is similar in all respects to those of Eureka, Nevada. The chambers and galleries have been dissolved out of the limestone by surface water carrying carbonic acid, and have been in subsequent upheavals opened by fissures, through which mineral solutions have flowed, more or less perfectly filling these cavities with ore deposits from such solutions. Very naturally these deposits lack the regularity and reliability of fissure veins, and they have in many cases, as the Emma, been completely worked out, so far as known; and yet the magnitude of some of these ore bodies, and the millions of dollars of bullion taken from them, prove that this class of deposits may be a source of great wealth. The great ore chambers formerly discovered here have been for the most part emptied of their contents. It is by no means certain, however, nor even probable, that all the valuable ore deposits are yet known, and there is encouragement for much and long-continued exploration in the extensive belt of country which is known to be metalliferous."

I am astonished that the distinguished Professor should have dealt so cavalierly and cursorily with such great interests as these of a district embracing about 20 paying mines, besides scores of others, some of them in as true fissure veins, and as distinctly not in limestone formations as any that can be found elsewhere. I am informed that the Professor came to Alta in the 11:30 morning train, dined at the inn, and then went up to the Emma mine and re-

mained there till the train left, at three o'clock the same day!

The Emma mine is in the heart of the Limestone belt, which has made this region famous for its great "chambers of ore." What he says on the subject of limestone formation may be weighed for its full value. But the statement, or inference, that there are no true fissure veins here is singularly incorrect. There are mines, paying mines, in true quartzite fissures with no limestone rock above them, or on either side of them, or beneath them as far as known, which are worked 500 feet down and nearly 1,000 feet in drift on the veins without a break in their continuity or general uniformity of direction, and growing richer as they go down. They are not the mines that startle the world with their sudden production. They are scarcely known abroad. They are not Ontario's that show that "nothing succeeds like success." But they are fissure veins hearing ore in the great quartzite and iron and granite mountains that may be seen on every side from where the Professor dined, and ought to have attracted the attention of a distinguished scientist even in a three-hours' visit to a mining camp. All these different formations are quite as conspicuous as the lower lime-capped hills near the Emma, and all of them are dotted with claims in true fissure veins not in limestone. There is great reason to believe that some of these fissure veins traverse the district below the limestone, and that with depth even some of the limestone-chamber mines may strike permanent fissure veins that have contributed to their richness. However that may be, if Prof. Newberry will revisit Little Cottonwood he can be shown plenty of true fissure veins that promise permanence of production of paying silver ore, with some promise of gold also.

This Little Cottonwood district has suffered immensely by the opprobrium attached to the management of certain of its great mines. Smaller mines that in other districts would invite capital to take hold of them, and where at moderate prices such capital could develop them thoroughly, so as to bring out generous returns, are here "unsight, unseen," by reason of the repressive influence of former unsuccesses of the stockholders in the collapsed bonanzas.

We naturally expect scientific men to examine such matters more calmly and dispassionately than other men; to take ample time for investigation of important matters, and not to pronounce hasty opinions on the mining geology of a great mountain district, on the strength of one little stroll after dinner to a single mine.

A scientific man owes it to his position not to fan the flames of speculation towards those districts where excitement already runs wild, as it did in this district in 1872, and now does in Leadville, Park City, and Bingham; but rather to hold the even balance of his judgment, to foster investment where property has less fictitious, in proportion to its real, business value.

Alta City, Aug. 18th, 1879. F. J. SCOTT.

American and European Archaeology.

A marked difference is observable between Europe and America with respect to the order of succession of the different prehistoric human "periods" to one another. In fact the succession is in the one exactly the reverse of what it is in the other. This difference is clearly expressed by the Rev. Stephen D. Peet in an article on "The Archaeology of Europe and America." "In Europe," he says, "the cave-hunter, who used bone implements, first departed; the fisherman of the kitchen-midden next passed away; the builder of the earth mounds followed with his rude weapons, and the inhabitants of the palafitte next disappeared; and last of all the Etruscan, the builder of the rude stone monuments. These Esquimaux, Basque Briton, Belgian, Celt, Saxon and Etruscan (?), are the successors to one another, while on this continent Quiches, Toltec, Aztec, Mound-builders, Red Indians, and Esquimaux are the silent throng who have reversed the column of departure. The Esquimaux was rudor than the Basque, and the Basque than the Briton, and so the order of departure gave place to a higher culture. In America the most civilized was the soonest removed, and the rudest remained the longest. The ancient city was deserted, but the pueblo remained; the pueblo itself changed inhabitants, but the Mound-builder remained; the Mound-builder was driven away, but the Red Indian continued; the Red Indian has disappeared, but the Esquimaux abides. The palaces of Palenque and Uxmal and the seven cities of Chichol are monuments of a civilization more ancient than the Mound-builders. The mounds of the Mississippi valley were doubtless erected by a more ancient race than the people who occupied at the time of their discovery. The Red Indians held an unbounded dominion more ancient than the villages which they inhabited, and the Esquimaux may possibly have once covered the whole land where all of these tribes so lately roamed, but the last survivor of all is now the rudest and wildest."—*Science Monthly*.

COPPER IN MAINE.—A copper belt some two miles long and from 200 to 400 feet wide, has been discovered about the middle of the southern part of Maine, directly on the coast. Some 20 miles to the northward of the copper belt, silver has been found in flakes, masses and filaments. A shaft has been sunk some hundred feet deep, and it is reported that the ore increases in richness with the depth.

Nova Scotia Mining Region.

A writer in the *Mining Record*, speaking of the mining affairs in Nova Scotia, says: "The whole Atlantic coast section of the peninsula of Nova Scotia proper, is believed to be of lower silurian age. This geological district is, at the western extremity of the Province, about 40 miles in width, but narrows gradually, although irregularly, as we proceed eastwardly, until, at Cape Corso, it runs out to a mere point. The total area of this district may be roughly estimated at nearly two-fifths of the whole area of the Province. Northward of this district and extending throughout the greatest length of the peninsula, with a generally easterly and westerly direction, are certain ridges usually classed as upper silurian and devonian; similar ridges, and also isolated masses of the same formation, form a large portion of the island of Cape Breton. These ridges and masses comprise the highest lands in the Province. Bounded by them on the south and elsewhere intersected or broken by them, we next find the carboniferous formation, which comprises all the remainder of the Province except a narrow band of new red sandstone, with associated trap, which forms the southern shore of Bay Fundy, and extends around the basin of Minas. The carboniferous district comprises a larger proportion of the total area of Nova Scotia than any of the others named."

"Gold is found throughout the widest extent of the lower silurian district, and in quartz beds—although usually called 'veins'—interstratified and conformable with the enclosing strata of quartzite and slate. Sometimes, although rarely, gold is found in true fissure veins of quartz. Indeed, such veins are rather of unfrequent occurrence. Where they are found connecting with, or intersecting, an ordinary quartz bed, it is usual—although not invariably the case—to find the quartz in the immediate vicinity of the point of connection, exceptionally rich in gold. These quartz beds, or auriferous lodes—locally called 'leads'—have a general easterly and westerly strike, conforming to that of the enclosing quartzite strata, and describing an approximate parallelism with the line of the Atlantic coast. The whole of the strata of this silurian district have been folded into numerous plaits, the axes of the plications of which also have a general parallelism with the neighboring coast line, consequently the quartz lodes, whilst they have all a nearly east and west strike, vary in dip from vertical to nearly horizontal; and so numerous are the folds already mentioned, that these extreme variations in dip sometimes occur within a few hundred feet of each other. As to the degree in which gold is distributed throughout this whole auriferous area, but little is yet known. The few 'gold districts' locally defined as such by the Provincial government, comprise in the aggregate only a small portion of the whole auriferous area, and even in the case of each of these 'proclaimed gold districts,' only a very small portion of the ground has yet been prospected. It may be remarked that, taking the city of Halifax as upon the meridian of the center of the whole gold-bearing tract, which it pretty nearly is, a large number of districts which have been proclaimed as such by law, and in which the principal mining operations have thus far been carried on, lie more to the eastward of that line than to the westward of it. It so happens that, in the western section of the Province explorations have never been prosecuted with much vigor. Yet it is certain that good prospects have been discovered in that section at numerous points extending to the extreme western shore of the Province."

GOLD DEPOSITS OF SACRAMENTO VALLEY.

While there seems to be no controversy as to the conclusion that the Sacramento and San Joaquin valleys occupy the bed of a former inland sea, situated between the Coast range and the Sierra Nevada mountains, which was filled by lava and debris from the adjacent mountains, it was considered doubtful whether the strata underlying these valleys contained any considerable deposits of gold or silver, because the mineral deposits were supposed to have been formed at a more recent period. Miners generally have believed that the ore veins were filled through crevasses either from melted quartz or liquid solutions containing minerals deep in the earth. The *Folsom Telegraph* says: "The recent developments through the enterprise of Mr. Wm. H. Dolman has established the fact that most if not all the gold and silver on the Pacific coast has been deposited from waters containing those metals in solution, as the lower strata of sand and gravel for a depth of 40 feet or more, is found to contain the crystallized sulphurets of those metals in abundance, and that they were formed where found is evident, from the fact that they not only adhere to the surface of smooth-worn pebbles, but fill the pores of the lignite or petrified wood found in those strata. That the evaporation from an inland sea in a climate like this, where scarcely a cloud is seen for six months in the year, would cause such a concentration as to produce such deposits, seems quite natural."

IMMIGRATION TO U. S.—A conference of delegates, representing 200,000 miners, was held in Manchester, England, on August 13th. A resolution was unanimously passed favoring emigration to the United States. If they all come, several of our undeveloped Western mines can be made to increase the wealth of the country.

MECHANICAL PROGRESS.

Water-Power Engines with Variable Stroke.

A Scotch engineer, Mr. John Hustie, says that about 13 years ago his attention was called to the necessity for some form of hydraulic power being substituted for horses in hoisting at the various sugar stores in Greenock; and he then designed a hydraulic winch mounted on wheels, and arranged to be connected by flexible tubing with the nearest water-main, so that one winch would be sufficient for several stores. In making the necessary calculations connected with this design he was surprised to find that the consumption of water was the same, whether a light or heavy weight was being raised; in fact, that as much water would be used in lifting the chain alone as was required for the greatest weight to be lifted. While thinking over this matter it occurred to him that if the stroke of the piston could be varied by some simple mechanical means, the difficulty would be overcome; but no encouragement was given to the employment of hydraulic power at the time, and the matter was laid aside until about three years ago, when the Greenock local authorities obtained an act of Parliament giving power to abolish the hoisting in the street by horses. As the employment of some form of hydraulic hoist thus became almost a necessity, his attention was again given to the principle, not only with a view to hoists, but for general purposes.

His first efforts were directed to obtaining a variable stroke of piston in a water engine. This was achieved in two ways; first, by means of a variable crank-pin, and secondly by employing a link as in the expansion gear of a steam engine. Both of these arrangements fulfilled the conditions required, but the variable pin was selected, as capable of being applied in a more compact form than the link. The principle was developed in three forms: (1) an arrangement with a screw, similar to the crank-pin of a slotting machine, which enables the engine to be set before starting so as to use a given quantity of water for any given amount of work; (2) an arrangement for varying the radius of the pin by hand while the engine was at work, which was a much more rapid way of effecting the change in the stroke than the former; (3) an arrangement for making the variation of the stroke automatic, the amount of work to be done by the engine being itself the means employed for effecting the change. This was by far the best method of the three. Engines on all these three principles have been constructed; 18 engines in all are now at work, and others are in course of construction. But the third or automatic method of varying the stroke is the most perfect form of this invention, and fulfills all the conditions necessary for the economical working of hydraulic motors with variable loads.

The consumption of water varies in proportion to the power required.

A NEW NUT MACHINE.—A new machine for sawing iron nuts has been invented in Springfield, Mass. The nut on which this machine is designed to work is of ordinary iron, but with two slots cut at right angles across the upper surface half as deep as the nut, so that when it is turned tight upon the nut the grip of the wrench closes up the apertures so much that it is impossible for the nut to work loose. The new machine will cut the slots in the red-hot iron as fast as it can be fed. The nuts are placed upon an iron plate in front of the operator, who with one hand pushes them forward till they drop one by one into an open box fitted to them, in which they are moved by gauge against a circular saw. A motion of the hand then turns each a quarter of the way round, when it is pushed against a second saw for the other slit. Thus, after the first one is cut into in one direction, two are slotted in the opposite direction by the same forward pressure against the saws. The saws, of soft steel, revolve 3,000 times a minute, the periphery traveling nearly four miles per minute, and the iron is sawed into as easily as a piece of wood on an ordinary machine. The machine will easily slot a ton of nuts, averaging 4,000 in number, in a day, and can probably be run up to a ton and a half.

PRESSURE REDUCER.—In order to relieve low-lying and branch mains, and domestic service pipes from excessive or unnecessary pressure, and thereby reducing the liability to bursts in the former case, and of injury to house fittings in the latter, a reducer has lately been invented in Glasgow, the action of which is as follows: The valve is perfectly balanced, so far as the inlet pressure is concerned; hence, if there be no pressure in the outlet main, it falls from its seat by its own weight and allows the water to pass; but when the pressure on the outlet main becomes sufficient to lift the valve, it forces it back to its seat, where it will remain until the pressure in the outlet is again reduced. All, therefore, that is necessary in order to obtain a fixed limit of pressure in the delivery pipe is to weight the valve, either by dead weight or spring and lever, to such an extent as to balance the intended pressure when acting on the valve. When this has been done, the pressure in the inlet may vary to any extent, but that in the outlet can never rise above the fixed limit.

TUBULAR PILES.—The *Scientific American* describes a novel and ingenious system of constructing and driving piles which has of late been introduced into practice by Messrs. Le Grand & Sutcliffe, of London, artesian well engineers. It involves a considerable departure from ordinary practice, inasmuch as the piles are driven intertally and at the bottom, instead of externally and at the top. The invention originated with the senior member of the firm, whilst the credit of some of the applications of the principle is due to the junior member. The piles, says *Engineering*, are tubular, and can be made of either wrought or cast-iron, and the thickness of the metal can be proportioned to suit the varying circumstances of construction. The lower end of the pile is made solid and pointed, and is generally of wrought-iron and steel-tipped. The piles are made in sections, which are screwed together by strong steel sockets or joint covers, which are barrel-shaped on the outside in order to diminish friction when being driven. The method of driving these piles is as simple as it is novel. Instead of the blows being delivered on the head of the pile, the driving force is expended just where it is wanted, namely, at the point. This result is attained by using an elongated cylindrical driving weight, which travels easily inside the tube. The weight is raised by means of rope or rods, and is allowed to fall on the flat head of the solid point, the pile thus forming its own guide for the driving weight. The effect of each blow is to drag rather than to drive the pile down. The point is swelled, and of sufficient diameter to effect a clearance for the joint covers, which have to follow it down. This pile fractures and passes through minor obstructions. The system commends itself for its simplicity.

A VALUABLE INVENTION FOR THE LAUNDRY. A man in Bridgeport, Conn., has invented a very simple but ingenious machine for ironing shirts. It consists of an iron framework about five feet long, three feet wide and two and one-half high. On the top of the framework is attached the iron, which is a hollow cylinder or roller, 16 inches long and 18 inches in diameter. This is provided with arms at each end, and, being attached to a crank, when in motion it rides back and forth on the framework. The cylinder is heated by gas. An attachment called the bosom board is connected at the end of the frame by hinges. The operator stands at the end of the frame and operates the machine very simply. The shirt is placed over the board the same as when ironed by hand, being drawn tight and smooth. The board is then thrown down in its place with the bosom upward. The heated cylinder passes over and finishes the work. This machine is capable of ironing from 500 to 600 shirts a day.

SCRAPING HOGS BY MACHINERY.—Man's inventive genius descends on many occasions to a porcine level. This remark is called forth by an invention used in Chicago in the packing houses of Armour & Co. for scraping hogs. As the scalded hogs pass over the revolving flukes they are scraped clean at the rate of ten hogs per minute, as we lately witnessed in company with some prominent agricultural gentlemen from the South who had come here to see the commercial emporium of the West, and the greatest live stock, grain and lumber mart of the world. And it is interesting to note the improvement which must have been effected in this marvelous machinery during the past year or so; for, if we remember rightly, the previous account of it was that large hogs could be scraped in ten seconds and small ones almost momentarily. So that there has been a saving of four seconds on big pigs, and possibly a fraction of a second or so on small ones.

GREAT PRESSURE UPON POWDERED SUBSTANCES.—Mr. Spring, a member of the Belgian Academy of Science, has made several very interesting experiments on the above subject with the following results, as reported in the *Chemiker Zeitung*: In a hollow steel bar, the sides of which were 64-100 of an inch thick, he subjected several powdered substances to a pressure of 20,000 atmospheres (133 tons per square inch). Molten and powdered saltpetre was pressed into a solid hard mass like porcelain. Powdered poplar wood was pressed into a block of much greater hardness than that possessed by the wood itself. The specific weight of the powder was 0.389, and that of the compressed block, 1.328. A powdered grindstone was transformed into a new stone of the same hardness as the original one. The same was the case with chalk.

IMPROVED RHEOSTAT.—This instrument, first invented by Sir Charles Wheatstone for putting a known resistance into a galvanic circuit and thus regulating the current's strength, has been improved by a gentleman in New York city. The bed plate is made of non-conducting material, and in an annular groove in its upper surface there is a film or plate of material that offers considerable resistance to the electrical current. Generally the groove is partly filled with plumbago. One end of the resistant is connected with a battery, and the current is completed through a movable key whose pivot is at the center of the circular groove. The key is provided with a roller which rests upon the plumbago and moves over its surface without abrading it. This rheostat seems especially adapted to the use of physicians and experimenters.

SCIENTIFIC PROGRESS.

Coal Tar Colors.

The wonderful growth of the industries engaged in the production of alizarins (artificial madder) and the coal tar colors generally, is the subject of a paper lately read before the Chemical Section of the London Society of Arts, by W. H. Perkin, F.R.S. The author, whose name is closely associated with the development of these manufactures in England, places the value of all the coal tar colors produced in Europe in 1878 at \$15,750,000, divided as follows:

Germany.....	\$10,000,000	France.....	\$1,750,000
England.....	2,250,000	Switzerland....	1,750,000
Total.....	\$15,750,000		

Germany has at present 17 coal tar color works, England has six, France five, and Switzerland four; besides which there are three works in Germany and as many in France which manufacture aniline in enormous quantities for the production of coal tar colors. Of alizarine the total production is estimated to be 9,500 tons, representing a money value of \$7,225,000.

The noteworthy and instructive thing about this whole subject is the fact that these enormous industries, which have sprung into existence since 1856, are entirely the fruits of theoretical researches in organic chemistry, and the extensive researches may be expected ere long to bear practical fruit, possibly even more valuable. Another subject toward which the eyes of chemists are turned with expectation is the artificial production of indigo upon the commercial scale. The distinguished German chemist, Beyer, has succeeded in putting out of the way the chief difficulty by actually producing it in the laboratory.

THE CHROMOGRAPH.—Mr. Albert Ungerer, of Vienna, has discovered a process of copying letters, which requires no more delicacy of manipulation than the drying of a letter with an ordinary piece of blotting paper. It consists of a slab of gelatinous material having the appearance of soft vulcanized india rubber, contained in a zinc tray. With this there is supplied a small bottle of ink—apparently an aniline compound—with which the circular or drawing to be reproduced is written upon any ordinary piece of paper, and permitted to dry. The writing is then placed face downward on the composition, and the hand is then passed lightly over it; after being left for a minute the paper is lifted, and every line and detail of the negative is found upon the composition with absolute precision. The reproduction can now be commenced; a sheet of ordinary paper is pressed upon the negative as in using blotting paper on a letter, and copies may be obtained consecutively to the number of 40 or 50. When the required number has been obtained, the negative is washed off, and the apparatus is ready for fresh work. As the copies can be obtained in several colors at one operation, it will be obvious that the apparatus will be of immense value in engineers' offices for reproducing sketches of machinery for the guidance of intending purchasers or manufacturers, and that it will be not less useful in mine and public companies' offices for the reproduction of reports and balance sheets for the information of, or to be revised by auditors or directors previous to printing them. As soon as known, the chromograph will certainly be almost universally adopted. It is being extensively introduced in England by Mr. Otto Lelm, of Farringdon street, E. C., London.

FIRE EXTINGUISHER.—Mr. Watson Smith discovered, several years ago, that crude ammonia water, or gas liquor, as it is called, acts like a charm in extinguishing a fire in a tar distillery. He now recommends that owners of cotton mills, and of tar works, varnish works, etc., should have on their premises a stock of about 1,000 gallons of this gas liquor stored in a tank or old boiler, mounted upon brick-work, and at such an altitude as to give pressure enough for a good jet service in case of fire. There is no reason why this cheap and efficient preventive of destructive conflagrations should not be generally adopted. It may be readily imagined, says Mr. Smith, how a jet of the liquor, thrown into a burning room, would act, the space being so enclosed, when the action is so powerful in a comparatively open space, and with such a refractory substance as burning pitch. It would seem, he adds, that the extinguishing power of the liquor would be even further called forth by a more intensely hot fire, for here, in all probability, the ammonia would be decomposed, and the generated hydrogen and nitrogen gases would help to swell the volume of non-supportive gas, displacing the air, and so choking out the combustion.

NEW EXPLOSIVE.—Prof. Emerson Reynolds, of Dublin, has discovered a new explosive, compounded of two substances, which can be kept apart without risk, and can be mixed as required to form a blasting agent. The powder is a mixture of 75 parts of chlorate of potassium with 25 parts of "sulphurea," a body discovered by Prof. Reynolds, which can be obtained cheaply from a waste product of gas manufacture. The new explosive is a white powder, which can be ignited at a lower temperature than gunpowder, and leaves less solid residue.

UTILIZATION OF EXHAUST STEAM.—According to the invention of Mr. N. W. Ericson, of Stockholm, he lets steam of higher pressure, or higher temperature, or both higher pressure and temperature than this pressure or temperature, or both, of the steam which is to be used in a steam engine or for any other purpose, pass into an apparatus for the suction and compression of elastic fluids, in order that the said higher or stronger steam may in such apparatus act as the suction fluid to the said spent steam; this suction and compression apparatus is further connected with the apparatus wherein steam is to be used in order that the spent steam may to a greater or less extent be drawn into the suction and compression apparatus when the acting or higher steam passes through it. The mixture of the acting or drawing steam and the spent steam passes through the delivery pipe of the suction and compression apparatus (and its continuation, as required) either to the place where the thus compressed steam is to be used, or else first through an apparatus containing saturated steam or water, or in so near connection with water that the steam, if in a superheated state, becomes more or less saturated or lowered in temperature, or else into an apparatus wherein the steam, by cooling, is rendered liquid, and the heat thereby given out is used for generation of fresh steam. This latter apparatus may be the steam boiler in which the acting superheated steam is generated, or another steam boiler vessel. The suction and compression apparatus may be any suitable suction and compression apparatus, such as an annular or other jet apparatus.

DRAPER'S RESEARCHES ON OXYGEN IN THE SUN.—Prof. Henry Draper, on the 13th of June, laid before the Royal Astronomical Society of London the evidence by which he claims to have demonstrated the existence of oxygen in the sun. A writer in the *London Times* (presumably Mr. J. Norman Lockyer) acknowledges the force of the evidence adduced by Prof. Draper. He says: "We think that most spectroscopists will admit that Prof. Draper does not pass beyond the limits of scientific caution in claiming that the coincidence shown in his photographs between the bright lines of oxygen and bright parts of the solar spectrum establishes the probability of the existence of oxygen in the sun. The burden of proof, or rather of disproof, should now fall on those who consider that the coincidence may, after all, be merely accidental. To us it seems that if such evidence as Prof. Draper has obtained is rejected, hardly any spectroscopic evidence can suffice to prove the existence of an element in the sun. We certainly have not stronger evidence in the case of sodium or magnesium, elements which every physicist regards as present in the sun, than Prof. Draper has obtained in the case of oxygen."

PHOTOGRAPH OF THE OXYGEN SPECTRUM.—The spectrum showed the lines described by Paalzow, O between b and E, O close by F, and O between F and G. A band of great intensity, which the author names O, lies near h. It is sharply defined toward the red end of the spectrum, but shades away toward the violet extremity. A double band, Os, near G, has the same character. In the spectrum of hydrogen the three already known hydrogen lines in the blue and violet were seen very distinctly, and also the red line, H_α, coincident with C of the sun. The fourth hydrogen line, coinciding with "h" of the sun, was observed with the naked eye by Paalzow and the author, on the application of the simple induction current, in opposition to the assertion of Lockyer that it is only visible at very high temperatures. Upon this assertion he found in part his supposition of the decomposition of hydrogen at elevated temperatures.—H. W. Vogel, in *Scientific American*.

BREAKAGE OF LOCOMOTIVE AXLES.—For some time it was suspected by the officers of the Frankfurt and Bebra railroad, Germany, that the practice of casting white-metal bearings around steel axles had been the primary cause of several breakages on the line, and a series of experiments were undertaken to ascertain the possibility of such being the case. By repeating the casting process a number of times on the same axle, it was found that in every case, and with every kind of steel tried, cracks appeared sooner or later, sometimes on the second trial, sometimes not till the forty-fifth. The white metal used contained 7 parts copper, 14 parts antimony, and 79 parts zinc, and melted between 810° to 932° Fabr. These experiments, therefore, tended to show that the plan of casting white metal round the axle is a fruitful source of danger.

NEW LAMP FOR PASSENGER CARS.—The well-known inventor, Geo. Westinghouse, has devised a lamp for passenger cars, which he thinks will supersede the ordinary oil lamp. It has been tried with satisfaction on the North British railway, Scotland, for some time. The use of the Westinghouse brake places at disposal a large amount of compressed air. When air is passed over benzine, or similar light hydrocarbons, it becomes saturated with the hydrocarbon vapor, and may then be burned just like ordinary illuminating gas. Beneath each car, therefore, a long cylinder is placed, which is filled with felt, saturated with petroleum. A current of compressed air, entering the cylinder at one end and escaping at the other, is led up to the roof of the car and burned in lamps of very elegant construction.

The Mining Share Market.

The election returns at the close of our last report seemed to affect the prices of stocks and produce a certain stagnation. The ability to control the water in the flooded mines sustained Comstock, although the market showed many signs of weakness, which were in a great measure dispelled by a stronger market, with a good demand for Comstock, a revival which was felt all along the line, and as we close our report the market is in a healthy condition, with a demand for stocks at advanced rates. The election of a conservative element to the Legislature has probably created more confidence than has been felt for the past year, and removed the fear of the destruction which threatened the mining stock business.

Bloody Canyon Mines.

We clip from the Mammoth City Herald, of a late date, the report of Superintendent A. Caldwell, on the mines of Bloody canyon, which is in itself an interesting sketch of this new district in Mono county. Mr. Caldwell says:

"I have made a close examination of the mines at the head of Bloody canyon on the east, and the headwaters of the Tuolumne river flowing westerly through the Yosemite valley. These mines are situated near the summit of the Sierras, on the westerly slope and 27 miles from Yosemite. They are without doubt on the mother vein of the Sierra Nevada mountains, the same mineral belt as Mammoth, North Fork, Prescott and Tioga. This mineral belt can be traced 50 miles and a continuous vein found. Its width of mineral belt will average one mile; its course is northwest by southeast and its pitch is easterly. At Mammoth the ores are free milling; gold is found one-third, silver two-thirds, and as you go north the metal runs into antimonial silver. This is the description of ores found in the mines of the headwaters of Tuolumne river. The outcrop commences at the head of Parker canyon, and follows the western slope of the mountains for a distance of six miles, and the vein can be traced the entire distance.

"At the Golden Crown the croppings show 200 feet in width. Ores from this mine assay as high as \$300 per ton at a depth of three feet below the cap. The cap rock is iron rock, and below this comes the antimonial silver ore. Following locations have been made: Golden Crown, Gem, New York, Big Blue, Mount Dann, Kalamazoo, New Brunswick, Ella Blose, Liberty, Enright and Silver Gray. The mineral belt lies in granite on the west side, and the east side of a belt is a quartzite and porphyry. There is only one vein running through the country. The facilities for working these ores cannot be excelled; wood and water are in abundance at the base of the mountain. A natural road leads down to Yosemite valley. I predict that in one year these mines will employ thousands of miners, and another grand field will be opened to the attention of our capitalists.

"I see no better field for an enterprising mining man on this coast than in these mines. The returns are certain, but of course capital must be had to open them up. It is no place for poor men this fall. The mines are new, and it is impossible to get employment; but next year there will be a splendid field for labor. The climate is healthy, and the winters are not severe. Living will be within the reach of the laborer, as everything is convenient, and all freight will come by Yosemite valley."

DISTANCE AND THE ELECTRIC LIGHT.—The Scientific American in its last issue says: "On the evening of July 12th, the Maxim electric light was put in operation on the tower of the Grand Union Hotel, Saratoga Springs, N. Y., with a view to test the extent of its illuminating powers. An open parabolic reflector was used—no lenses. The light was turned toward a spot in Ballston Spa, New York, 7½ miles distant. So powerful was the light, so accurate the focusing and alignment, that the designated place in Ballston was instantly illuminated, so that ordinary print could be read, the time seen on watches, etc. The night was clear, still, and dark. The experiment was made at 9½ o'clock p. m."

DIMOND, the defaulting ex-Treasurer of the Massachusetts Missionary Society, has been committed to prison at Boston in default of bail.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

Items.—*Dispatch*, Sept. 6: The Tallman mine has nearly finished sinking the extra hundred feet which they have been engaged for some time past. The rock taken out from the bottom looks well, and the prospect of making this a successful mine is much brighter now than it ever has been before.

CALAVERAS.

OWEN MINE.—*Chronicle*, Sept. 6: The batteries are kept constantly employed, rock being taken from both the 1400 and 1500 levels. The new hoisting works, at the new shaft on the Alexander mine, are completed, and sinking has been commenced.

CLARK-UP.—J. F. Veldt, Esq., proprietor of the Mammoth hydraulic, finished cleaning up this week. We are not at liberty to give the figures, but the amount of gold recovered is large. Mr. Veldt has made a very successful season, and although the water has failed for the present, he will continue work putting the Mammoth in condition for active operations when rains come again.

EL DORADO.

SACRAMENTO MINE.—*Republican*, Sept. 4: This mine is located about a mile and a half north of Shingle Springs. The rock assays well; even at the surface it is sold for \$20. It is owned by Mr. Stewart, of Sacramento, who is already erecting a large furnace and works suitable for the mine. He proposes to work the mine by what is known as the Robertson process. This is considered a vast improvement on the old cumbersome mills and at a cost of \$3 per ton, 90% of the fire assay can be obtained. An assay office will be erected near the furnace works and mining tests will be made at a cost of \$1.00 per pound, \$15 per ton.

Items.—*Mountain Democrat*, Sept. 6: The Eagle mine at Grizzly Flat has a large and strong ledge, the prospecting of which gives promising results. A thorough development is to be made at once, capital having been secured for that purpose. The "Eagle" is on the same ledge as the celebrated "Mount Pleasant" mine. The Golden Gate mine is located upon the north bank of Canyon creek, near Jones' Hill village. There is a handsome five-stamp quartz mill on the mine. Tunnels and crosscuts have been run along the ledge, which satisfy the owners that there are many years steady work yet ahead. The ore taken from the tunnel and crosscuts runs from \$40 to \$75 per ton. Georgia Slide is a permanent mining camp. The Beattie mine, owned by Harkins, Beattie, (Gardner) and Thurston. This mine in character is bedrock, in places interspersed with quartz seams and strata of porphyry. The mode of working is by running tunnels or powder drifts to be blown up, then, after breaking with hammers these large rocks by hydraulic process, the debris is washed through the flume. The result pays the owners handsomely, who have thus worked it since 1854. The mine is now worked to a depth of 150 ft. The Reinhardt mine, owned by Jo. Reinhardt and others, adjoining the Beattie is worked in the same manner, and pays satisfactorily to the owners, who have worked it constantly since 1850. The Blue Rock mine adjoins Reinhardt's, and is owned by the Flynn Bros. This mine is the same in character as the others, and pays with like satisfaction to its owners.

INYO.

MODOCK.—*Independent*, Sept. 6: South drift, 300 point, 22 ft; north drift, 300 point, 15 ft; north drift, 300 point, 10 ft; north crosscut, 1100 point, 16 ft, and south drift, 1100 point, 10 ft. Total length of south drift, 100 ft; north drift, 100 ft; north crosscut, 100 ft; north drift, 300 point, 160 ft; north crosscut, 100 point, 20 ft; and south drift, 1100 point, 160 ft. Have started a crosscut west from drift north, 300 point, and shall further explore the ore body. We have been running in on this drift. Have had ore from the first 15 ft to present face, 57 ft. North drift, 800 point, still presents the same appearance, carrying clay seams in face, and holding its ore well toward the lowest ledge on the face. North crosscut 1000 and south drift 1100 point continue to improve as we advance. Face of latter is in crystallized lime and manganese, looking favorable for ore.

INDEPENDENCE TUNNEL.—At a distance of some 50 ft from the mouth of this tunnel the miners have cut into a blind ledge containing some very fine looking ore, but, as yet, nothing is known of its extent. At a point 100 ft further it will cross the lowest ledge on the face, having a surface outcrop, one of Superintendent Holt's original locations, the ore of which assays as high as \$180 per ton.

MONO.

STANDARD.—*Bodie News*, Sept. 7: North drift, 385 level, is in 307 ft, this ledge in this drift is 3 ft wide of good ore. Have started a crosscut from this drift 353 ft north of the main east crosscut; the rock here is at present very hard. In the slopes the ledge continues to look well, and is from 5 to 15 ft wide of high-grade ore. The south drift, 050 level, is in from the winze 30 ft, the ledge being 4 ft wide and looking well. The top raise from this level has reached a height of 130 ft; the ledge at this point is very wide of fair milling ore. The west crosscut, 300 level, is in 75 ft; formation continues to get harder. The ledge in this main east crosscut is about 10 ft wide of rich ore. In the slopes, 350 level, south drift from this ledge, is from 5 to 12 ft wide of good ore. The ledge in the Golden slopes is 3½ ft wide, and is looking about the same as usual. The pumping engine is now in place. Work on machinery and buildings at the new shaft is nearly finished. The new hoiler house, and car track to tramway, will be completed in a short time.

South Noonday.—Engaged in sinking a winze from the north drift, on the ledge, which continues to improve as distance is made. The vein is now 3 ft between walls and of a fine character of ore which will do to mill. The character of the ledge is a soft decomposed quartz and clay, resembling that found in the Noonday and other mines in the immediate vicinity. The tracing done on the surface at this mine has resulted in uncovering a fine and paying ledge, which will average from this grass roots 4 ft in width.

MARYLAND CON.—Main double compartment shaft down and timbered 180 ft, and will be completed to its lower level in about 15 days.

VORTEX.—Winze from the north drift, on the 200 level, has been advanced and is paying the week; ledge in the bottom is two feet wide of good ore.

UNIVERSITY.—New shaft down 106 ft, showing a formation of porphyry with heavy seams of quartz and clay. Indications are favorable to the discovery of a large ore body at an early date.

SOUTH BULWEN.—Leds on 350 level is 3 ft wide, showing a fair character of ore encased between good walls. North drift, 200 level, has been advanced 2½ ft, and has advanced 10 ft, making a total of 29 ft; ledge 2½ ft wide of good milling ore. The west crosscut on the 420 level has been advanced 0 ft through very favorable formation, having passed through several fine strata of quartz.

WEST PACIFIC.—The ground very fine. Progress during the week 11 ft. The old portion of the shaft, about 35 ft, to the level of the ledge is not considered safe, although the lagging is quite sound. A small vein, prospecting well in gold, has been struck at the bottom of the shaft.

MONO.—*Chronicle*, Sept. 6: The joint crosscut has been run a total distance of 405 ft. A drift has been run south on the Boyd ledge a distance of 34 ft. A winze has been sunk on the above ledge 34 ft, and as depth is attained the ledge widens, showing good ore. Two large hoilers have been added to furnish additional steam power.

BLACKHAWK.—The shaft is now down 28 ft below the 300 level, and is going down at the rate of two ft a day. The bottom is entirely in vein formation. The winze on Warren vein is down 150 ft below 820 level. Crosscutting

has commenced, east and west, to cut veins on both sides of the winze. Winze on west vein, near the west line of the claim, is down 55 ft below 320 level. Vein continues about 2 ft wide, regular and well defined between two solid walls. Average assays, \$20, and improving as depth is attained.

On our visit to the mine yesterday we found them putting on a new cable 700 ft in length.

TIOSA.—Shaft down 66 ft, in hard rock. The drift is in about 320 ft, in fair working condition. The general drift, south, on vein No. 3, 5-10 level, is in 75 ft, with a ledge in face of drift 3 ft wide of good milling ore. The north lateral drift in same vein is in 65 ft, with 2 ft of ore in face. Have started a vertical winze on 620 level to strike the No. 3 vein, which will occur at no great depth.

RED CLOUD.—Working on 250 level, and running two drifts. South drift, west crosscut in Red Cloud ledge, is in 18 ft, with 2 ft of fair ore.

CHAMPOS.—Sinking winze on 400 level. It is now down 32 ft, in all the way, and which is widening out in the bottom. The south crosscut is in 62 ft, and also in all the way. Everything about this mine is running smoothly.

MAMMOTH.—*Lake Mining Review*, Sept. 6: The Bonanza tunnel is in 357 ft. Crosscut No. 3 has been advanced over 36 ft, the whole distance in fine ore. The ore vein becomes richer as work progresses.

MONTICELLO.—A large quantity of fine milling ore is on the dump.

TAHOE BLUE.—The face of the drift is in 140 ft, with stringers of quartz coming in. The ledge is 30 ft distant.

NAPA.

QUICKSILVER.—*Callistoga*: Mining business at Callistoga begins to look up a little as the weather gets cold. Francis will soon work his claim day and night; and it begins to look as if the Ida Esley might receive some attention again soon. Work is set on other claims will commence at an early date. During the week ending Tuesday, Sept. 24, the large amount of 41,732½ pounds of quicksilver were shipped from Callistoga to San Francisco.

ITEM.—*Register*, Sept. 6: About a year ago J. H. Francis, of Callistoga, commenced prospecting for gold and silver on the 2500 level, 1300 ft above that town. Until lately, however, he has not been able to work very energetically, but a month or two ago a man in his employ came down from the ranch and told him good quartz had been found, and Mr. F. immediately repaired to his claim, to find the report correct. He immediately set men to work, and has now quits an extensive tunnel in the mountain.

When in 30 ft some of the rock was sent to San Francisco, and an assay obtained that warranted a following up of the indications. This has been done and the rock improves in richness as the work progresses. Men are now at work on the tunnel continuously, day and night, and there are those who think Mr. F. is in a fair way to strike a bonanza. The claim is on the east side of the valley, one and a half miles above Callistoga.

PLACER.

Items.—*Herald*, Sept. 6: The Heenan and Molin quartz mine, on Rock creek, now worked by E. W. Roberts, is reported as yielding some very excellent ore. Messrs. Breece & Wheeler have about completed their new track and other preparations for the winter's run on their claim at Bath.

Their prospects are said to be good for a large area of the "ore." Messrs. Clark, Hemley & Beckett are also pushing work ahead on their tunnel, and are quite sanguine of success.

NEVADA.

WASHOE DISTRICT.

GRIM.—*Gold Hill News*, Sept. 8: During the past week the main incline has been sunk and timbered 14 ft and is now 27 ft below the 2400 level. The material passed through and now showing in the face continues to be a favorable looking vein matter carrying streaks of clay and quartz. On the 2500 level the north drift has been advanced 35 ft, making the total length from the main east drift 253 ft, passing through bird's-eye porphyry with clay streaks. The east crosscut from the end of the main east drift is now in 19 ft, showing a favorable vein porphyry. The north drift on the Hardy vein has been advanced 20 ft, and is now 45 ft north of west crosscut No. 1; still showing low grade ore. On our 2000 level the joint Mexican crosscut has been advanced 20 ft, and is now 24 ft; total length, 108 ft. The material passed through continues a vein formation, showing more quartz than at date of last report. The stopes are yielding good ore.

UNION CON.—The joint Mexican crosscut on our north line has been extended 3 ft; total length, 30 ft. The material passed through continues to be a soft matter, showing streaks of quartz and clay. Work has been resumed in the raise from our 2500 level (2500 ft) from the main east drift, designed to connect with the Union shaft. It is now up 40 ft above that level, which leaves 74 ft to go before making the connection with the shaft.

CON. VIRGINIA.—During the past week 1,215 tons of ore have been extracted. On our 850 level in the joint California west crosscut we penetrated beyond the drift with the diamond drill 42 ft and struck clay, through which we could not pass. The drill has been taken out and drifting resumed in the face of the drift. The south lateral drift is now in 20 ft, passing through a vein formation showing streaks of clay. On the 1050 level we have started an upraise at a point 60 ft east of No. 2 winze, which will explore the country east of the ore stopes. On the 2160 level the east crosscut has been extended 29 ft—total length 190 ft—and continues in a favorable formation.

CALIFORNIA.—During the past week 981 tons of ore have been extracted. On our 850 level, in the joint Con. Virginia crosscut west, we penetrated beyond the face of the drift with the diamond drill a distance of 42 ft and struck clay, through which we could not pass. The drill has been taken out and drifting resumed in the face of the drift.

MEXICAN.—On our 2100 level the joint Ophir west crosscut has been extended 24 ft, and is now in 108 ft from the main north drift. The joint Ophir vein formation showing more quartz than at date of last report. The joint Union Con. winze on our north line has been sunk and timbered 16 ft; total depth, 52 ft; showing a soft vein formation in the bottom, and carrying sufficient water to interfere with our progress in sinking.

SAVAGE.—The 2200 lateral drift, connecting with the Hale & Norcross, has been entirely drained from water. The drift has been taken out and drifting resumed, excepting the northern portion near our incline, carrying the incoming flood of water which covers the bottom of the drift a few inches. The water stands in our station about three ft, the drift being considerably higher than the station. We cannot enter this station or lower our pump any further, owing to the excessive heat and the gas escaping from the incline. The temperature taken this morning at the coolest point at this pumps is 140° Fahrenheit.

CON. IMPERIAL.—The joint vein being sunk on Alpha-Imperial line from the 2000 to the 2135 level has been advanced 21 ft, making total depth of same to date 72 ft. Upraise started during past week from 2135 level has been extended 12 ft. There have been started two crosscuts on the 2000 level. The first is a vein formation showing the other about 200 ft south of said line, each having been advanced to a distance of 10 feet.

UNION SHAFT.—During the week we have sunk and timbered our shaft 32 ft, making a depth of 80 ft below the Sierra Nevada 2000 level. The raise from the Sierra Nevada 2200 level, designed to connect with our shaft, is now up 40 ft, leaving 74 ft yet to raise before making a connection with the shaft we expect to accomplish by the 25th inst. On the 1600 level the west drift to connect with the Union Con. east drift has been extended 23 ft, making a total length of 113 ft, passing through hard, blasting porphyry.

SIERRA NEVADA.—Very good progress has been made in the upraise from our 2200 level to connect the Union shaft with the Hale & Norcross. The vein is very rich, and the sinking of the Union shaft. When this shaft is completed to this level the cost of handling the water in the Sierra Nevada incline will be very much reduced.

GOULD & CURRY.—During the week ending yesterday the 1700 joint east crosscut was advanced 30 ft; total

length of drift 1,217 ft. The G. & C. and B. & B. joint shaft was sunk and timbered 15 ft; total depth to date, 730 ft. Machinery for the new pump hoist is arriving on the ground and will be set up together with the pumping engine, as soon as the foundations are completed, which will be some time during the present week.

NORTH BONANZA AND FLOWERY.—The water struck a few days ago in the bottom of this shaft is gradually diminishing, but not sufficiently, however, to resume sinking. The ledge in the 400 has not been cut yet, notwithstanding we have expected to do so every day of the past week. The crosscuts on the 300 of the Flowery are showing better; also, one of the exploring drifts going north from this crosscut. In the North Bonanza 300 crosscut No. 1 the ore is showing much better than at last report.

TIOSA.—West drift, third station, has been advanced and timbered 5 ft. At a point 65 ft in on west drift drifted south 23 ft through quartz and porphyry, quartz giving low assays. Thirty-seven ft have been added to working above second station, passing through quartz and porphyry, quartz giving fair assays.

SILVER HILL.—This past week our 1300 crosscut has been extended east 58 ft; whole distance from incline, 282 ft. It is in porphyry, mixed with streaks of low-grade quartz; very little water.

BULLION.—The north drift on the 2400 level has been advanced during the past week 23 ft in Bullion, growing, through material about the same as that mentioned in my last report. The incline winze has been sunk 14 ft, making its total depth 111 ft. The material penetrated is hard, vein matter.

ARGENTA DISTRICT.

ITEM.—*Tybo Sun*: We learn from a private letter that the Oliver Twist mine in the above district is looking well. The return from the assay at date, \$41, and silver \$847, total \$888. About next month they will ship some ore here to the Tybo Con. for reduction. The New Philadelphia company mine, Bismarck, is opening out well and has yielded a good lot of ore now on the dump.

BELMONT DISTRICT.

Items.—*Courier*: The Belmont mine is looking very well. About 500 tons of good milling ore have been taken out. The Alexander mine is proving to be one of the very best in Nye county, and the output is regular. As the mine is opened up it shows constant improvement, both in quantity and quality of ore.

EUREKA DISTRICT.

ETREKA CON.—*Sentinel*, Sept. 2: The ore bodies are showing considerable strength. The surface shaft is down 105 feet in hard limestone. Indications of ore in the west cliffs of 13th and 14th levels.

PARADISE DISTRICT.

RATTLER MINE.—*Silver State*, Sept. 4: This mine is now producing, with a small force of men, about two tons of ore per day. Last month the ore sampled \$54 per ton. The ore as now taken from the mine assays, from battery samples, from \$75 to \$200 per ton.

BULLION OF PARADISE.—This company has struck the ledge through the tunnel. Crosscut now in 13½ ft. The quartz shows silver thoroughly mixed with a number of varieties—black sulphurets, ruby and chlorides predominating. A specimen taken from the lowest depth—about 100 ft—this afternoon, will assay into the thousands. The ore from this mine works easily by the wet process from 75 to 78%, proving it a very fine milling ore and much more economically worked than if it required roasting.

PARADISE MINE.—Never looked so prosperous as now. About 50 men are working in all departments.

ITEM.—*Silver State*, Sept. 3: General Clarke received a note from Paradise to-day informing him that the lower tunnel on the Bullion of Paradise mines tapped the ledge on Monday and has since been run into it 1½ feet without striking the hanging wall. The ore is very rich and the strike is the most important yet made in the mine.

PIOCHIE DISTRICT.

Items.—*Eureka Sentinel*, Sept. 3: We hear that a vein of ore, 12 ft in width, has been discovered in the neighborhood of Wilson's ranch, by Mr. Woods and his partner. The discovery of the vein, the ownership of which was lately decided in court, belongs to the district of Sol. Grinnell and others, will immediately be opened up, a force of men having already been sent out to the mine for that purpose. Work has also been commenced on some other claims in that district by McDonald & Webster.

RUBY HILL DISTRICT.

ITEM.—*Eureka Sentinel*, Sept. 6: Four men at the Connor mine get out 100 tons of ore per month at present rate of working.

WILLOW CREEK DISTRICT.

ETHAN ALLEN.—*Eureka Sentinel*, Sept. 6: T. J. Harlan, assayer at Paradise Valley, who recently visited the Ethan Allen mine, on Willow Creek, reports it to be one of the largest ledges ever discovered in the country. It is located on Willow creek, where there is plenty of fuel and water for reduction works, six or seven miles from the Ohio mine. The ledge crops out about 100 feet wide on the surface, and is prospecting by a tunnel which has been run 30 feet into the ledge, showing ore all the way. The ore assays from \$30 to \$800 in silver per ton, the average being considerably over \$100.

WHITE PINE DISTRICT.

ITEM.—*Bodie News*, Sept. 5: The latest from Geesela is to the effect that 41 tons of ore from the Monroe & Lincoln, taken as it comes, worked \$30 to the ton, and 30 tons of ore from the Crescent, one of the Eagle mining company's mines, worked \$16 to the ton. This, for gold ore, is not to be despised, even in a good mill, but when extracted by means of an excuse for one, might be called extraordinary.

ARIZONA.

Items.—*Tucson Star*, Sept. 4: News from Oro Blanco says that a fine line of ore has been struck in the Idaho, one of the Flood & Kirkpatrick mines. We learn from Mr. Geo. Hoag, superintendent of the Grisham mill, that prospects in Oro Blanco district were never more encouraging than at present. Preparations are being made by several companies to put large forces to developing some of the rich properties of the district. Already some of them have begun. He says that not less than 150 men will be turning out ore before the end of the month. From every mining district in the country we have the most encouraging news. From north, south, east and west we hear of new finds, rich developments and good sales. Dos Cabezas, Swissalm, Dragon, Tombstone, Huachuca, Whetstone, Patagonia, Davis Canyon, Cahabi, Arivaca, Oro Blanco, Montezuma, Papago, Santa Catalina, San Pedro and other districts in the country are showing right on.

YAVAPAI CON.—*Arizonian*, Sept. 6: The Tiger and Tip Top mills are running and paying. It is thought that the Peck mill will shortly start up. Masterson's Turkey Creek mill is, we learn, running on good ore. Messrs. Gosper & Lount have the machinery for their mill on this ground. Several areas are at work on the Laramie creek, and are not at all pleased up, when the result in gold from two tons of rock placed on who saw it. Mr. Earp is sinking on what promises to be a good gold and silver-bearing lode, a few miles west of Prescott. Rock from it may be seen at this office. Robert Connel and David Grubb are delighted with results of recent assays of rock from their "Fire Tree" lode, in Haysanapa district.

"The Fire Tree" lode, in Haysanapa district, is not at all pleased up, when the result in gold from two tons of rock placed on who saw it. Mr. Earp is sinking on what promises to be a good gold and silver-bearing lode, a few miles west of Prescott. Rock from it may be seen at this office. Robert Connel and David Grubb are delighted with results of recent assays of rock from their "Fire Tree" lode, in Haysanapa district.

MONAHUE CON.—Letters from gentlemen of Mineral Park, county seat of Mohave, give good news. Mr. Hardy has placed a force of men on this Fairfield mine. The Keystone miners are taking out a great deal of fine ore. The first stamp mill started on the 22d inst. Mr. Barry has charge, and is working ore from this "63" mine. The mill to Cedar Valley district is said to be running. Another report is that the Signal mill is also at work.

[CONTINUED ON PAGE 172.]

How Our Ancestors in the Stone Age Made Their Implements.

[Read before the California Academy of Sciences, August 4th, by HON. B. B. REDDING.]

Flint, obsidian, chert and other hard stones having a conchoidal fracture, manufactured into forms to be used as axes, chisels, knives, scrapers, spear and arrow-heads, are found in nearly all parts of the world. They are almost the only remains of a race of people who inhabited the earth at a period so remote that they were contemporaneous with the woolly elephant, the cave bear, the Irish elk, and other animals now extinct. These implements are often found in connection with the remains of these and other fossil animals. In one instance, in Denmark, a stone arrow-head was found imbedded in the bone of a deer, the whole family of which has been so long extinct that they are only now known from their fossil remains. The people who made these stone implements lived in Palestine ages before Tuhah Cain, and in Egypt long before the first Pharaoh. Their flint knives, axes and arrow-heads have been found in Europe from Greece to Norway, and from France to the Steppes of Russia. In Asia, from India and the Malay Archipelago to Japan and Kamtschatka. In America, from Greenland and Alaska south through the United States, the West Indies, the valley of the Amazon, and Peru to Terra del Fuego. They seem to prove that man was originally a savage; that he lived by fishing and the chase, and that civilization is the result of a long, slow and tedious process of evolution.

There is great similarity in these stone weapons and implements wherever found throughout the world. A spear-head or scraper, an arrow-head or celt from England could not, by its shape or peculiarity of manufacture, be distinguished from similar instruments found in Denmark, Palestine, Japan, or South America. The stones used might differ, but the mode of manufacture and general shape are nearly always the same. How our pre-historic ancestors could have made these stone implements ages before the discovery of the use of bronze or iron has been the subject of many speculations among archaeologists, and many theories have been advanced in support of these speculations. The general conclusion has been that they were chipped into the shapes we find them by blows from small stone hammers. It is, however, proper to state that Mr. John Evans, Sir John Lubbock, Mr. A. Morlott and other writers on pre-historic remains, have suggested that the observations of travelers as to the modes pursued by savage nations in similar work might afford a correct solution.

The theory that they were manufactured into the shapes we find them by blows from stone hammers was generally received until after the publication, in the *Overland Monthly*, of the observations of Mr. E. G. Waite, and the late B. P. Avery, and in the Smithsonian reports of a letter of General George Crook, all of whom had had an opportunity to observe Pacific Coast Indians manufacture stone implements, and chip them into perfect shapes without the aid of stone hammers. As, however, these Indians used iron or steel in their work, obtained from white men, it was thought they might have changed the processes pursued by their ancestors. From a late newspaper paragraph I see that Mr. F. H. Cushing, who is connected with the Smithsonian Institute, by independent observation, has arrived at the conclusion that the stone implements were not chipped into shapes by blows, but that the small flakes were broken out by pressure, and that to prove his theory, he made a flint chisel, chipping it into shape by pressure with the aid only of a piece of hard wood.

Having had an opportunity to see a stone arrow-head made by a man, practically still living in the Stone Age, without the aid of any implement other than those found in a state of nature about him, and taking notes at the time of each act of manipulation and every process, I have thought a record of what I saw, added to those made by other observers, might have some value in determining the processes used in similar work by our remote savage ancestors.

Prior to the close of the Modoc war the Wintoons, or McCloud River Indians, were without firearms. Up to that time the few settlers who reside about the base of Mount Shasta made it a rule to permit no Wintoon to carry a gun. As there are no agricultural lands and no mines on the McCloud river, the Wintoons were left in almost undisputed possession of their prolific hunting grounds and to the inexhaustible supply of salmon and trout with which that river abounds. The Wintoons had but little contact with Americans until after Mr. Livingston Stone established a station on the river for the taking of salmon eggs for distribution by the United States government. Very few of these Indians as yet have guns; their principal reliance in the chase being upon their primitive but powerful bow and arrows. The arrow-maker is still a man of great importance in the tribe.

While visiting the United States fishery a few days since I expressed a wish to Deputy U. S. Fish Commissioner Livingston Stone, who has acquired a knowledge of the Wintoon language, that one of the best arrow-head makers of the tribe should make in my presence a stone arrow-head, using only such tools and implements for

the purpose as were in use by the Indians before their contact with white men. These people are only now emerging from the Stone Age, and a record of their manufacture of stone implements may give an illustration of the methods pursued by our ancestors in the Paleolithic Age, 10 or 12 or more thousands of years ago, when they lived upon the products of the chase of the fossil deer, the anurochs and the cave bear.

Promptly at 3 o'clock came Consolulu, an old man between 68 and 72, grey haired, but erect and vigorous. He had been for many years chief of the tribe, and was elected chief when a young man because alone and unaided he had killed a grizzly bear with his bow. He brought, tied in a deer skin, a piece of obsidian weighing about a pound; a fragment of deer-horn split from a prong lengthwise, about four inches in length and half an inch in diameter, and ground off squarely at the ends, this left each end a semi-circle; two deer prongs (*Caracus Columbianus*) with the points ground down into the shape of a square sharp-pointed file, one of these being much smaller than the other. He had also some pieces of iron wire tied to wooden handles, and ground into the same shapes. These he said he used in preference to the deer prongs, since the white men came to the country, because they were harder and did not require sharpening so frequently. When asked where he obtained the obsidian, he answered from a place on the north side of Mount Shasta—about 60 miles distant; that, in former days, the land where it is found was claimed by the Yreka Indians, and as this stone was wanted by the Trinity Indians, the Yrekas and the Modocs, as well as the Wintoons, it was rarely obtained without a battle. The piece he had was a light blue in color, and he valued it at \$20; he stated that if it were white it would be worth \$40 or \$50. I could not learn that white obsidian is harder, or is worked with greater ease. Its increased value is probably based on its greater rarity. After stating that in battle he had been twice wounded with arrows, once in the shoulder and once through the calf of the right leg, and showing the scars above the ankle where the arrow had passed through, missing the bone, and been drawn out at the other side, and further stating, with evident gratification at the recollection, that while the arrow was still in his leg, he sent one of his own into the throat of his opponent, from the wound of which he had died to death in a few minutes—he commenced the operation of making a stone arrow-head. Holding the piece of obsidian in the hollow of his left hand, he placed between the first and second fingers of the same hand the split piece of deer-horn first described, the straight edge of the split deer horn resting against about a fourth of an inch of the edge of the obsidian, this being about the thickness of the flake he desired to split off. Then, with a small round water-worn stone, which he had selected, weighing, perhaps, a pound, he with his right hand struck the other end of the split deer horn a sharp blow. The first attempt resulted in failure. A flake was split off, but the blow also shattered the flake at the same time into small fragments. He then repeated the operation, apparently bolder the split deer-horn more carefully and firmly against the edge of the large piece of obsidian. The next blow was successful. A perfect flake was obtained, showing the conchoidal fracture peculiar to obsidian. This I purchased, and instructed him to split off another from which to make the arrow-head. He repeated the operation, and was again successful, and I have no doubt he could, with only an occasional failure, have split up the whole piece in a few minutes into shapes for spear-heads, knives and scrapers. The shape naturally taken by the obsidian when split off in this manner is that of a spear-head, and it could be put to use for this purpose with but slight alteration. The thickness of the flake to be split off depends upon the nearness or distance from the edge of the obsidian on which the straight edge of the split deer-horn is held at the time the blow is struck.

The flake having been obtained, I watched with much interest and attention the process of working it into an arrow-head. He now squatted on the ground, sitting on his left foot, his right leg extended in a position often assumed by tailors at work. He then placed in the palm of his left hand a piece of thick, well-tanned buckskin, evidently made from the skin of the neck of a deer. It was thick, but soft and pliable. On this he laid the cake of obsidian, which he held firmly in its place by the first three fingers of the same hand. He then rested the elbow on the left knee, which gave the left arm and hand holding the flake firm and steady support. He then took in his right hand the larger of the two deer prongs—which, as has been stated, had its point sharpened in the form of a square file—and holding it as an engraver of wood holds his cutting instrument, he commenced reducing one edge of the circular form of the flake to a straight line. With the thumb of the right hand resting on the edge of the left palm as a fulcrum, the point of the deer prong would be made to rest on about an eighth of an inch or less of the edge of the flake, then with a firm downward pressure of the point a conchoidal fragment would be broken out almost always of the size desired. The point of the deer prong would then be advanced a short distance, and the same operation repeated until in a few minutes the flake was reduced to a straight line on one edge. As this operation broke all the chips from the under side of the flake, if left in this condition, the arrow-head would be unequally

proportioned, that is, the two cutting edges would not be in the center. He, therefore, with the side of the deer-horn, firmly rubbed back and forth the straight edge he had made on the flake until the sharp edge had been broken and worn down. The flake was now turned end for end in the palm of his hand, and the chipping renewed. When completed, an equal amount was taken from each side of the edge of the flake, and the cutting edge was left in the center. It was now plain that the straight edge thus made was to be one side of the long isosceles triangle, the form of the arrow-heads which is used by his tribe.

With the flake of obsidian firmly held in the cushion of the left palm, and the point of deer-horn strongly pressed on the edge of the flake, the effect was the same as the blow which split the flake from the larger piece. While, however, he was not always sure of the effect of the blow in splitting off the larger flakes out of which to make the arrow-heads, he in no instance appeared to fail in breaking out with the point of deer prong the exact piece desired. The soft, thick, pliable piece of tanned deer-skin on which the flake in his left palm was held may have added to the cushion, but seemed to serve no other purpose than save his hand from being cut by the countless sharp chips as they were broken off. One of the long sides of the arrow-head having been thus formed, the flake was turned over and the other side formed in the same manner. As, however, very much more of the obsidian had to be chipped away he brought more pressure upon the point of deer horn and broke out larger chips until the flake began to assume the shape desired, when the same care was exercised as when the first straight edge was made. In breaking out large or small chips the process was always the same. The pressure of the point of the deer-horn on the upper edge of the flake never appeared to break out a piece, which on the upper side reached beyond where the point rested, while on the under side, the chips broken out might leave a space of twice the distance. Invariably, when a line of these chips had been broken out, the sharp edge was rubbed down, the flake turned end for end, and the chipping renewed on the other side. By this process the cutting edges of the arrow-head were kept in the same line. The base was formed in the same manner. No lines were drawn, but he would occasionally look at his work as it progressed and chip on one side or the other to keep their proportions equal. The base of the arrow-head, opposite the point, when finished, is inserted in a slot made in the end of the wooden shaft, and is firmly tied by deer sinew. To hold the arrow-head firmly to the shaft, and to prevent the three-d from interfering with the penetrating power of the arrow, a slot about one-fourth of an inch deep is chipped into both cutting edges of the arrow-head, about one-fourth of an inch above the base. This causes the arrow to look as if it were barbed, but the object seems only to be to provide means by which the arrow-head may be firmly fastened to the shaft, at the same time avoiding the making of any obstruction to the penetrating or cutting power of the arrow-head. The chipping out of these slots was the last operation to be performed. It seemed to be more difficult than any other part of the work, and I thought in this would be the danger of the loss of all the patient labor that had been expended. In practical operation it was the simplest, safest and most rapid of all his work. He now held the point of the well-shaped arrow-head between the thumb and first finger of his left hand, with the edge of the arrow-head upwards, the base resting edgewise on the deer-skin cushion in the palm. He then used the smaller deer prong, which had been sharpened in the same form as the larger one, but all its proportions in every respect were very much smaller. Its point could not have been larger than 1-16th of an inch square. He rested this point on the edge of the arrow-head where he desired to make the slot and commenced sawing back and forth with a rocking motion, the fine chips flew from each side, the point of deer-horn descended, and in less than a minute the slot was cut. The arrow-head was turned over and the same operation repeated on the other edge. It seemed that, by this process, if he so desired, the arrow-head could have been cut in two in a very few minutes. He now examined his work in the strong sun light, and, being satisfied, handed to me the completed arrow-head. It had taken him 40 minutes to split the two flakes from the larger piece of obsidian and chip one of them into the arrow-head. A younger man, equally expert, would probably have done the work in half an hour. When I came to the purchase of the arrow-head and flake, I found they would cost 75c, payable in shells, *-dentalium entalis*,—which he estimated more highly than their value in money. The worth of the flake and arrow-head was not based on the time or labor employed, but upon the value of the obsidian, as he offered for a dollar's worth of shells to give me 10 arrow-heads of the same shape and size made from the bottoms of glass ale bottles.

The celts, knives, chisels and scrapers of the Stone Age are all much simpler and more easy of manufacture than these semi-barbed arrow-heads.

I doubt if stone hammers were used in their manufacture other than to split off the flakes from a large piece of flint or obsidian, and when thus used the blow was communicated through the split deer-horn or a piece of hard wood in the manner I have described. The blow from a stone hammer direct on the flint or obsidian

would be very uncertain in its results, even in the most skillful and practiced hands. With the split deer-horn the thickness of the flake and probable length could be determined with tolerable accuracy. Probably large chips could be broken from the edge of a flake by a slot in the end of a deer's horn, as is now practiced by the natives of Alaska with a walrus tusk, used as I have seen window glass broken with a key; but an arrow-head is too small and delicate for either operation.

I cannot but believe our pre-historic ancestors in the Stone Age used the same processes as were followed by Consolulu; and that, in describing what he did, I have told how the first ancestor of

"The ancient arrow maker,
Made his arrow-heads of sandstone,
Arrow-heads of chalcedony,
Arrow-heads of flint and jasper,
Smooth and sharpened at the edges,
Hard and polished, keen and costly."

Victoria Regina.

[Written for the PRESS by JEANNE C. CARR.]

The credit of the discovery of the queen lily is accorded to Doctor, afterward Sir Robert Schomburgk, the elder brother of a very remarkable family of naturalists. He commenced his career as modestly as our poet naturalist, Muir, and spent some years in business before receiving his call to explore and to write. He was a tobacco planter and manufacturer in Virginia, where he failed, went to the West Indies, and was employed in botanical and geographical explorations until 1840, when the English Geographical Society sent him to make certain surveys of the boundaries between British Guiana and Brazil. Schomburgk found the great lily in the river Beriche, in English Guiana, and gave it its royal name, which has been corrupted in consequence of misprint to the present form, "regia."

Several years earlier, D'Orbigny, a French naturalist, who, if I am not mistaken, was a member of the Academy, and died not many years ago in Paris, found the mammoth fleets of the leaves in the Parana and mentioned the discovery in his letters home. The wife of D'Orbigny visited California in 1870.

But the original discoverer of the marvelous plant was Hencke, a German traveler, who found it in the year 1801, in the river Mamore, one of the great affluents of the Amazon. He said the vision caused him such a transport of delight and admiration that he "fell upon his knees and expressed aloud his thanks to God for this manifestation of the power and magnificence of his works." I repeat this pleasant story on the authority of a brother of Sir Robert Schomburgk, who is the curator of the Royal Botanic garden of Adelaide, South Australia.

Hencke having died before the birth of the royal lady for whose advent the great lily and Dr. Schomburgk were waiting, it lay hidden in the inhospitable, yet magnificent solitudes which it adorns until 1841, when its seeds and dried specimens of leaf and flower were sent to England as a christening present, perhaps, to the baby princess soon to become Empress of Germany. The seeds were planted in the noble conservatory at Chatsworth, watched over by Sir Joseph Paxton; artists and botanists vied with each other in making it famous; the finder was made a knight for his pains; no one can say that the welcome it received was not worthy of its rank in the floral world. A mammoth colored atlas of the Victoria regia, which Col. Warren and possibly others in San Francisco possess, furnishes the best pictorial representation of the entire plant. There is also a large folded plate in one of the volumes of the *Botanical Magazine*, which is to be found in the library of the Mechanics' Institute. It first blossomed in the United States in the conservatory of Caleb Cope, in Philadelphia, in 1852, when hundreds visited it. It has since flowered in many other places, and its cultivation is not more difficult than many another "water bean," for such it is after all.

When I shut my eyes, and think how those still, dark water pastures must look, with the great leaves, the pure huds, the snowy blossoms just opened, the rosy masses of fading bloom, I am in sympathy with the rapture of Hencke, oppressed with the wealth of nature with no one but God to speak to in those vast solitudes. Sometimes I think, how long the Lord and the lily had waited for the eye to see and the heart to feel this beauty. I remember, too, another lily bloom, which Audubon found and described in his lonely wanderings among southern lakes and lagoons, the yellow *Nymphaea*, which has lately been rediscovered and credited to him. This rare lily has bloomed in the garden of Jackson Lewis at San Jose. I wonder what manner of lilies Audubon and Hencke perchance are gathering beyond the river of death; and so I leave this web of fact and of fancy to be finished by my reader, who, having seen the Victoria regia blooming in the Park conservatory, will be unwilling to rest without knowing more of it and of all the lotus-blooms, which the wisest of ancient peoples chose to symbolize things sacred and eternal.

Sacramento, Aug. 25th, 1879.

SUCCESS OF ELECTRIC LIGHT.—The English Parliamentary Committee's report on electric lighting says, that sufficient progress has been made to encourage the belief that electricity has a future for illuminating and as a source of mechanical power.

THE ENGINEER.

Atmospheric System for Working Mines.

The *Annales des Mines* describes a radically new mode of lifting minerals and maintaining a sufficient ventilation in the workings of deep mines, which has been lately introduced in the Hottinguer shaft of the Epinac collieries (Saône et Loire).

This shaft now exceeds 1,963 feet in depth, and will be sunk to 3,279 feet.

The coal trams, to the number of nine, are placed one above the other in a cage, which is provided at each end with a piston, working in a large tube reaching the whole depth of the shaft. The cage is raised or lowered by creating a partial vacuum or a plenum above the piston by means of a powerful air-pump. The arrangement consists of either a single tube, in which a cage alternately rises and descends, or of two tubes, coupled together, in one of which a train of empty trams descends while a full tram is being raised in the other. When two tubes are used the air pumped from that in which the full train is being lifted is delivered into the other, in which the empty train is descending, and in which there is already a partial vacuum, instead of into the atmosphere, and the weights of the trains thus balance each other, the net load of coal only having to be raised by the engine.

The air of the mine, which fills the lower part of the tube as the train rises, is blown out to the surface through an escape pipe as it descends, and the ventilation is thus to some extent assisted.

The tube used in the Hottinguer shaft is single, 5 feet 3 inches in diameter, of wrought iron, about 5-16 inches thick. It is in lengths of 4 feet 3 inches, bolted together, the joints being made with rings of caoutchouc a quarter of an inch thick. The heads of the rivets are countersunk on the inner side.

The sections of the tube carrying the doors and other fittings are in cast iron. At each loading and discharging place, or station, there are three doors in the tube, one above the other, spaced the height of three trams apart; so that when the cage is in one position the first, fourth and seventh trams are opposite to the doors; when it is lowered through the height of a tram, the second, fifth and eighth come opposite to the doors, and so on.

The cage is retained in any position by stops worked from the outside, and is readily lowered or raised at the stations, to bring any tram opposite to the doors, by admitting air over it, or by opening a communication between the tube above it and the exhausting engine. The cage is stopped without shock, at the ends of its travel by the cushion of air in the closed ends of the tube; and to admit of stopping at intermediate levels, as well as to guard against accidents, a sliding partition is fitted in the tube immediately below each station, except that at the bottom, which is open so long as the cage is below, but is closed when it has passed. The position of the cage, with its pistons, during the ascent or descent, is indicated in the engine-house by a series of barometers showing the pressure of air in the tube at points 100 meters (109 yards) apart. As the pressure below the cage is equal to that of the atmosphere, while a partial vacuum is maintained above it, the barometers show at once whether the cage is above or below the point at which each of them is connected to the tube.

To allow the pistons attached to the cage to fit the tube, even where this is not cylindrical, as at the doors, one of them, that above it, is made double, consisting of two pistons spaced at a distance apart greater than the height of a door, but less than the length of tube between two doors. The pistons are packed with leather, and the tube is lubricated with water mixed with a little soap and oil.

The weight of the tube, 603.30 meters (659 yards) high, now in use, is 345 tons. It was completed in July, 1876, and has been worked regularly ever since. It is served, provisionally, by two pumping cylinders, 5 feet 3 inches in diameter by 2-foot stroke, driven by gearing from the winding engine formerly in use. With this pumping power, the trams lifted are each of 6 tons gross weight, carrying 3 tons of coal. The vacuum maintained in the tube is equal to a column of 9.4 to 9.8 inches of mercury; the speed of the train is 1½ inches per second; the friction is scarcely perceptible; and the leakage of air past the pistons does not exceed 14 to 17 cubic feet per second.

The work done in lifting the coal is 28% of the indicated power of the engine, while with the same engine, when winding up by a rope, it did not exceed 16%.

Large engines, of 730-horse power, are being constructed to work the tube, and with these a train of a gross weight of ½ tons, carrying 4½ tons of coal, will be brought up at each lift. It is estimated that the consumption of coal for the boilers of the winding engine, in lifting from a depth of 1,000 meters (1093.6 yards), would be 10% of the quantity raised if ropes were used, but will be only 3% by the pneumatic system, even with a single tube. This is a saving of 145 pounds of coal per ton of coal lifted, equal to 6.6 pence per ton, valuing the coal used for the boilers at 8 shillings per ton. With an output of 450 tons per day, and reckoning 280 working days in the year, this is equal to an economy of £3,528 per year, in boiler coal alone.

USEFUL INFORMATION.

Lime and Hydraulic Cement.

From various authorities, among which may be named, Vicat, Burns, Haswell and Gen. Gilmore, the following statement of the characteristics of various kinds and qualities of lime and cement has been compiled:

1. The rich limes are the purest metallic oxide of calcium we possess, and the purer the carbonate of lime from which they are obtained, the more distinctly marked are appearances from which they derive their name. These are that they augment in volume to twice their original bulk, or even more, when slaked in the usual manner, and that they will not set (harden) under water if not mixed with any other mineral material, even though left immersed for years.

2. The poor limes are those which do not augment in bulk at all or only to a trifling degree, when slaked. They do not set under water any more than the rich limes.

3. The moderately hydraulic limes set under water in from 15 to 20 days, but do not become very hard. The change of bulk they undergo in slaking is the same as that of the poor limes, but never equal to that of the richer varieties.

4. The hydraulic limes set in from six to eight days' immersion, and continue to harden for some months.

5. The eminently hydraulic limes set within three or four days, and become quite hard in a month.

A classification of rocks with reference to chemical examination is as follows:

1. Pure calcareous rocks, or those containing from 1% to 6% of silica alumina (common clay), magnesia, iron, etc., either separately or in combination, give rich limes upon being calcined.

2. The limestones containing soluble silica in the state of sand, magnesia, the oxides of iron and of manganese, in various respective quantities, but limited to between 15% and 30% of the whole mass, yield poor limes.

3. The limestones containing silica in combination with alumina, magnesia and traces of the oxides of iron and manganese, in various respective proportions, but within the limits of from 8% to 10% of the whole mass, yield moderately hydraulic limes.

4. When the above ingredients are present in the proportions of from 15% to 18%, but the silica in its soluble form always predominating, the limestones yield a hydraulic lime.

5. When the limestones contain more than 20%, and up to 30% of the above ingredients, but with the soluble silica in the proportion of at least one-half of them, the limestones yield eminently hydraulic limes.

The experiments upon which the above conclusions are based appear to show that limes owe their hydraulicity, or power of setting under water, to the presence of a certain quantity of clay, and sometimes, but rarely, to the presence of a certain quantity of pure, soluble silica; and upon that principle a large proportion of our hydraulic cement, or water lime, is manufactured by mixing common fresh burnt lime with burnt clay and grinding them together, generally in the proportions of 20 parts of clay to 30 parts of very rich lime, but the proportions vary with the qualities of limestones and clays found in different localities.

WOOD STAINS.—To turn oak black so as to cause it to resemble ebony, the wood should be immersed for 48 hours in a hot saturated solution of alum, and then brushed over several times with a logwood decoction, prepared as follows: Boil one part of best logwood with 10 parts of water, filter through linen, and evaporate at a gentle heat until the volume is reduced one-half. To every quart of this add from 10 to 15 drops of a saturated solution of indigo, completely neutral. After applying this dye to the wood, rub the latter with a saturated and filtered solution of verdigris in hot concentrated acetic acid, and repeat the operation until a black of the desired intensity is obtained. To imitate rosewood a concentrated solution of hypermanganate of potassa is spread on the surface of the wood, and allowed to act until the desired shade is obtained. Five minutes suffice ordinarily to give a deep color. A few trials will indicate the proper proportions. The hypermanganate of potassa is decomposed by the vegetable fibers with the precipitation of brown peroxide of manganese, which the influence of the potassa, at the same time set free, fixes in a durable manner on the fibers. When the action is terminated, the wood is carefully washed with water, dried, and then oiled and polished in the usual manner. The effect produced by this process on several woods is remarkable. On the cherry, especially, it gives a beautiful red color.—*Scientific American*.

TRANSPARENCY OF METALS.—With the aid of electricity films of several metals of such minute thickness as to allow the light to pass through them can be produced. An electric current is passed into a wire of one of the metals, that extends into a glass tube containing rarefied air or gases. The particles of metal that the electric current loosens from the wire are deposited on the sides of the tube and form a transparent film. The light that passed through gold was a very handsome green, silver produced blue, copper, light green, platina, bluish gray, zinc, dark bluish gray, and iron, brown.—*Chemiker Zeitung*.

A NEW MATERIAL.—An invention lately brought out in England, consists in mixing the dust of coal with an extract obtained from boiling ordinary seaweed or other similar vegetable matter, producing when boiled, a similar mucilaginous or adhesive solution. In carrying the invention into effect they first boil seaweed or other vegetable product capable of yielding, when boiled a mucilaginous or adhesive solution, and then mix coal-dust with the said solution in the ordinary manner in which cement, mortar, or any other similar material is mixed. The combined materials are then molded to any desired shape by hand, or by means of a brick-making or other suitable machine. The same solution, when combined with sawdust or other suitable material, may be formed into blocks for filtering purposes.

TO BLEACH STRAW.—Straw goods are bleached by submitting them to the action of the vapor of burning sulphur—or better, to the vapor of burning bisulphide of carbon. The straw, which must be perfectly clean, must be well moistened with pure soft water before submitting to the sulphuric oxide. The bleaching is carried on in tight wooden sheds. Straw may be bleached by chlorinated lime, but the fiber is liable to be somewhat injured thereby. Moisture the goods thoroughly in a strong aqueous solution of the bleaching powder (defecated), and then pass them through a bath of sulphuric acid diluted with about 20 parts of soft water. Repeat if necessary, and finally rinse thoroughly in water containing a small quantity of sulphur or hyposulphite of soda.

FORMATION OF ACETIC ACID PREVENTED.—It is said that common rosin prevents the formation of acetic acid in fermented liquids without having any disturbing effect on the process of alcoholic fermentation. The peculiar effect of the hop may be due, it is suggested, to its resinous matter rather than to its oils. Rosin is added to sweet wines in Greece.

TO PRESERVE AUTUMN LEAVES.—Spread the fresh leaves and press them in a suitable dish, with alternate layers of fine sand, which is thoroughly dry, and as hot as the hand can bear. When the sand has cooled they may be removed, smoothed under a hot iron, dipped for a moment in clear French spirit varnish, and allowed to dry in the air.

CHEAP BABBITT METAL.—A cheap Babbitt metal is made by melting separately four pounds copper, twelve pounds tin, eight pounds regulus of antimony. Pour the antimony into the tin, then mix with the copper, away from the fire, in a separate pot, and add twelve pounds more tin.

ANTISEPTIC ACTION OF ACIDS.—According to Sieher a relatively small proportion of acid, 0.5%, prevents putrefaction. This property is conspicuous in the mineral acid, and in acetic acid. Lactic and boric acids are much less effective.

GOOD HEALTH.

Chronic Rheumatism.

Prof. Alfred Stille, of the University of Pennsylvania, lecturing to his medical class, says: Chronic articular rheumatism may follow the acute form if not treated promptly and effectively; or it may occur as a distinct disease, characterized by stiffness and pain in the joints. If the disease appears originally in its chronic form, the joints do not usually undergo any change, but if the chronic stage follows an acute attack they are quite stiff.

(The chronic form is sometimes called "cold" rheumatism.) In this case the sensibility to cold and dampness is rendered morbidly acute. When exacerbations occur the disease assumes a subacute type, and all the joints become red, swollen, and warm. The pain is aggravated by heat. These exacerbations are of indefinite duration.

If the joints have not become positively deformed a cure may be hoped for. If a cure is not established the functions of the joints will never be re-established. These deformities are, in reality, lesions of the soft parts.

In the treatment of the febrile or subacute form, he recommends the local application of heat, the use of the alkalies, moisture, local stimulants, narcotics, and sudorifics; in the chronic form, alteratives, and such local stimulants as camphor, turpentine, ammonia, chloroform, iodine, and even blisters and moxas. In the case of the elbow, knee, and ankle joints a very excellent form of local alterative is sulphur in fine powder laid between the folds of linen and applied to the joints. In all cases, passive motions should be practiced to prevent permanent stiffness of the parts, and the induced current of electricity should be frequently passed through the affected joints.

Local hot baths are peculiarly efficacious in chronic cases: they may consist of hot or warm water, air, or steam; and in this connection some of the saline, alkaline, or sulphureted mineral waters may be employed. The hydro-pathic pack is often serviceable. The sweating induced by all such baths is exceedingly useful; and this should be supplemented by horseback

riding and by walking. If the reaction which follows it is vigorous, sea-bathing is sometimes excellent.

Where the fibrous investments of the joints are swollen, iodide of potassium is effective. All general systemic disorders should at the same time be sedulously treated with iron, quinia, and other general tonics. If there is any hilousness, purges should be judiciously administered.

Should all other measures fail to relieve the patient, he should at once be sent to spend the winter in some tropical climate.

Rheumatic gout (more accurately, rheumatoid arthritis) should be confounded neither with chronic articular rheumatism nor gout proper. Change of structure in the joints themselves is the essential symptom of this disorder; whereas, in rheumatism the changes occur in the surrounding ligaments. It may be distinguished from gout by the absence of dusky veins and edematous swellings. Unlike both those diseases, rheumatoid arthritis begins and progresses very slowly. At first, one or more joints are swollen; then they become deformed by a bony swelling external to the joint itself. Passive motion of the affected part causes pain and a crackling sensation. In time the joints may become disarticulated. This disease is never fatal, but it causes a great deal of suffering, and the limbs are twisted into almost impossible positions. The treatment consists in rest and all possible hygienic comforts, good food, fresh air, plenty of sunshine, and ample clothing. The pain should of course be eased, if possible, by anodyne applications. In some cases good seems to follow the painting of the affected parts with a very strong tincture of iodine; but no internal drug-giving has in Dr. Stille's experience, been attended with the slightest benefit.

About Poisons.

A poison is defined by Webster as "a substance which, taken into the stomach, mixed with the blood, or applied to the skin or flesh, proves fatal or deleterious; anything infectious or malignant."

Almost everybody knows that arsenic, strychnine, opium and chloroform are poisons; but many people are not aware that many medicines are more or less poisonous, although large doses may be required to cause death or immediate and violent sickness.

The *Journal of Materia Medica* warns us against several "every-day poisons." The first one mentioned is the bitter almond. A very little of the essential oil used in flavoring cakes or candies, brings out, on sensitive children, an eruption like nettle-rash, or may bring on vomiting and fatal exhaustion.

Fish of certain kinds are always poisonous in hot countries, and other kinds are more or less poisonous to certain individuals. Many persons have been made sick at one time or another by white fish, salmon or lobster; and the instinct is wise which avoids such articles for ever after.

Lead poisoning from water-pipes, acting slowly and subtly, often goes unrecognized, and is dubbed "malaria."

Pencils, nighled by school-children five days out of seven, cause disorders which may be falsely charged to bad ventilation or too hard study.

Baking-powders are apt to contain alum, which it is injurious to swallow. And the syrup which we eat upon our morning cakes may be adulterated with chloride of tin, and cause dyspepsia. While many substances are not poisonous, in the absolute sense of the term, they are deleterious, and affect the human system in a variety of ways. Some persons are not affected by the free use of that which would produce fatal results in others. There are also chemical changes which occur in combining poisonous or injurious substances with other and harmless elements, which deprive the former of their baneful effects. All who desire health and comfort should carefully study the effects of food taken into the stomach, and if deleterious will soon manifest itself, and consequently should be avoided.

OXYGEN IN HYDROPHOBIA.—Oxygen as a cure for hydrophobia, is stated to have proved successful by the *Lyon Medical*. The case is reported by Drs. Schmidt and Zeheden, from Russia. The first symptoms of rabies appeared 17 days after the injury. The patient was made to inhale three cubic feet of oxygen, and two hours afterwards he was in a state of perfect calm. Two days afterwards the symptoms of rabies re-appeared, and another inhalation of oxygen was administered with the same success. This time the inhalation was continued for 45 minutes. A slight dyspnea, which persisted after the disappearance of the graver symptoms, was treated for three weeks by the mono-bromide of camphor.

COFFEE AND NERVOUSNESS.—We have it on the authority of Dr. Bock, of Leipsic, that the nervousness and peevishness of our times are chiefly attributable to tea and coffee; the digestive organs of confirmed coffee drinkers are in a state of chronic derangement, which reacts on the brain, producing fretful and lachrymose moods. Ladies addicted to strong coffee have a characteristic temper, which might be described as a mania for acting the persecuted saint. Chocolate, be adds, is neutral in its psychic effects, and is really the most harmless of our fashionable drinks.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Twenty-Nine Years a State; New Zealand gold fields; City Foundry Notes; A Ten-Foot Extension Rule, 161. The Week; The Yellow Jacket Hoisting Engines; Amalgamating Chloridized Ores; Concrete, 168-169. Measurement of Earthquakes, 163. The Mechanics' Fair, 172.
ILLUSTRATIONS.—Derickson's Ten-Foot Extension Rule, 161. Measurement of Earthquakes, 169.
CORRESPONDENCE.—Poisoned Water; Utah—Little Cottonwood, 162.
MECHANICAL PROGRESS.—Water-Power Engines with Variable Stroke; A New Nut Machine; Pressure Reducer; Tubular Piles; A Valuable Invention for the Laundry; Scraping Hogs by Machinery; Great Pressure upon Powdered Substances; Improved Rheostat, 163.
SCIENTIFIC PROGRESS.—Coal Tar Colors; The Chromograph; Fire Extinguisher; New Explosive; Utilization of Exhaust Steam; Draper's Researches on Oxygen in the Sun; Photograph of the Oxygen Spectrum; Breakage of Locomotive Axle; New Lamp for Passenger Cars, 163.
MINING STOCK MARKET.—Sales of the San Francisco, California and Pacific Stock Boards; Notice of Assessments, Meetings and Dividends, 164.

Business Announcements.

Trall Hygienic Sanitarium, Dr. D. C. Moore, S. F.

The Week.

It would seem from our exchanges that more energy has been displayed in counting the contents of ballot boxes than the weekly yield of bullion. There is no lack of activity either in prospecting or working. Those of the hydraulic mines, dependent upon a natural supply of water, have suspended operations for the present. In Amador county the Talisman is showing indications of a successful mine. In Calaveras the Gwin mine keeps its batteries constantly employed on ore from the 1400 and 1500 levels. The Mammoth hydraulic has finished cleaning up, with large returns. Mining in Napa county is improving, a new and rich find in quartz having been made by J. H. Francis on his mountain ranch near Calistoga. Prospects for a large yield of ore are good on Rock creek in Placer county. Large and strong ledges are being developed in El Dorado county, particularly in the Sacramento mine, near Shingle Springs, which bids fair to be the richest in the county. The prospecting of the ledge in the Eagle mine, at Grizzly Flat, gives promising results.

The mines of Nevada are constantly improving; most of the districts furnishing increased advantages in quality of output.

The water in the flooded mines of the Comstock is under subjection, and prospecting will soon be in order. Leaving the domain of steady-going mines in California and Nevada, we find that startling discoveries and rich developments are being made in Utah, Colorado and Arizona. The mind wonders at the enormous assays which nearly equal the ton of ore pound for pound, but relief is experienced when later reports show from \$30 to \$60 per ton as the regular yield. The Alder region in Montana is prospecting very rich, many valuable gold lodes having been recently discovered. Some etir has been created by the discovery of a rich deposit of gold in Calipoola mountains, 40 miles east of the Oregon & California railroad, in the northern part of Douglas county, Oregon. Two miles of sluices have been built, and 100 miners are panning out from 30c to \$1 per pan.

The Yellow Jacket Hoisting Engines.

Immense Machinery Built by the Risdon Iron Works.

One of the largest of the large hoisting outfits for mines purposes ever built on this coast has just been completed at the Risdon Iron Works in this city, for the Yellow Jacket mine, in the Comstock. The whole outfit weighs some 350 tons. For beauty of finish, and style in appearance, the machinery excels any yet made here. A noticeable feature is the excellence of the very large casting comprising part of the works, and the care which has evidently been given to all details of the work. These hoisting engines and plant combine all the latest improvements of every kind, and every care has been taken in construction and finish; the whole being done in a thoroughly workmanlike manner, which reflects credit on the builders, exciting the admiration even of experts in that line.

The hoisting machinery consists of a pair of direct-acting engines, complete, with reels, brakes, etc. The two engines work on one crank-shaft, and are 28 feet apart between centers. The engine frames are of the Corliss, or circular patterns, and about 24 feet long between the front ends of the cylinders and where the frames join the pillow-blocks. The cross-head guides are cast with the frames, and are provided with oil-gutters or channels to catch oil drip.

The cylinders are 28 inches in diameter, with eight feet stroke of piston. The exhaust chests are cast on the side of the cylinders, and low enough to have the valve-seats below the bottom part of the cylinder. Each engine has its pillow-block cast in one piece, and bolted to the frame, with side and bottom braces. The center pillow-block is bored to 21½ inch diameter, and has a 32-inch length of journal.

The crank-shaft is turned bright. It is 19 inches in diameter at the ends, and 21½ inches in diameter in the center. The method of construction of the crank and crank-plates is peculiar. There is a crank at each end of the shaft, made of wrought-iron, and 4 feet long from center of shaft to center of pin. The crank-hub is 36 inches in diameter, and 17 inches thick. Each crank is bored, turned and planed on faces and sides, and on each side is forged a tongue to fit in the crank-plates. These crank-plates are of cast-iron, circular in form, and each made in two pieces. When the two pieces are bolted together the disk is 13 feet in diameter and 14-inch face. Each plate has a recess to fit the tongue of iron left on each side of the crank. These plates are turned and finished on faces and edges, after the crank is put in place between the two parts, which are bolted together and enclose it. This is an expensive method of construction, but a most effective one, the forged crank then being imbedded in the cast plate.

The crank-pins are of steel with steel keys. The connecting rods are 22 feet long, finished bright. The two cross-heads are wrought with cast-iron shoes, the shoes being fitted with brass gibs. The piston-rods are steel, 6 inches in diameter. The pistons are 12 inches deep on the periphery, and 15 inches deep through center, each piston having outside and inside packing rings expauded by heavy tempered steel springs. The pistons have solid blocks on the bottom instead of springs. The cylinder heads project six inches inside the cylinder, and are made concave. The outside covers of the back heads are turned and polished, and have upon them, in brass letters, the names of builders and designer. All the glands of both engines, and the bottoms of all stuffing boxes, are properly hushed with brass and oiled.

The admission valves are of brass, of the Cornish pattern, with 9-inch openings. The exhaust valves are of the American double-disk pattern.

The links are solid, wrought-iron finished and case-hardened. They get their motion from the four valve eccentrics. Both links are operated by levers, shafts and quadrants. The expansion of steam is controlled by Crose's variable cut-off. All the working pins through the valve gear are made of steel. Each engine has a 10-inch Cornish valve for throttle working on a separate chest.

There are two reels with twelve movable arms each. The reels are six feet in diameter and seven-inch face. They run upon eight bearing brases, all adjustable. The reel arms are made adjustable to take in various widths of rope. The brake-wheels are made 15 feet in diameter and 12-inch face. The clutches are 60 inches in diameter and 29 inches long. They are handed with two wrought-iron bands. The clutches are worked by two hydraulic cylinders, eight inches in diameter and eight-inch stroke.

Each brake-wheel has three brakes on each side and one at the bottom. These side brakes are models of strength. They consist of two upright wrought iron trussed arms, 19 feet long, connected on top by a double adjustable rod. The under shoes are 9 feet long and 12 inches wide. The bottom brakes are wrought iron straps. The straps are wood covered, and are operated by a combination of levers. In addition, each crank-plate has a wrought-iron strap brake. Each reel is furnished with one of Behr's patent spiral drum indicators, four feet in diameter and six feet in length.

This machinery was built from designs of W.

H. Patten, Esq., consulting engineer of the Yellow Jacket company. The Risdon Iron Works took the contract to finish it in 125 working days, and have completed it 20 days ahead of time. The hoisting works are intended to reach a depth of 4,000 feet, and will start work at a depth of nearly 3,000 feet. The engines have been set up at the Risdon Iron Works this week, where they occupy a space of 36 feet in width, and 56 feet in length. These works also made the four boilers, 54 inches by 16 feet, of the usual style, with the exception that they were made of steel. This is the largest job turned out at any of our foundries this season, and in some respects, the largest set of hoisting works ever built on this coast. The engines will be taken down on Saturday for shipment.

Amalgamating Chloridized Ores.

Usually, in amalgamating chloridized ores, salt water has been added to the pulp in the amalgamating pan, and this water, combined with the chloride of sodium contained in the pulp, formed a brine or saline solution that materially aided the amalgamating process by holding the compounds of the base metals in solution, while the mercury combined with the gold and silver. Each fresh charge of pulp is treated with a new charge of salt water, so that only the salt contained in each charge or portion of brine was utilized for this purpose. It is now found, however, that much better results are obtained by a repeated use of the brine thus formed, instead of depending solely upon the salt contained in each charge of pulp.

The ore of silver are first chloridized, whether with or without gold, by roasting them in the ordinary way with common salt, and they are then amalgamated with mercury in wooden pans or barrels, out of contact with iron, but with copper linings or balls, using in the operation instead of water the liquors from a previous amalgamation. The liquore, after the amalgamation is completed, are carefully preserved for use with fresh portions of the ore previously chloridized by roasting with salt.

The advantage is thus secured of a strong brine for holding in solution the compounds of the base metals, and amalgamation of the precious metals is favored more than can be done with water or the simple use of weak brine, which is ordinarily used with the mercury in working chloridized ores; for the strong brine, holding in solution other chlorides and compounds of base metals, extracted from the previous charges of the ore and used out of contact with metallic iron, acts upon portions of ore not perfectly roasted, and causes a larger yield of the precious metals than can be obtained by the use of salt water, as in ordinary amalgamation.

This process has been made the subject of a patent obtained a short time since through the MINING AND SCIENTIFIC PRESS Patent Agency, by Mr. James O. Stewart, of Georgetown, Colorado. It is more particularly intended as an improvement on the Douglass, Hunt & Stewart patent of June 9th, 1874, which differs materially, of course, from the original Hunt & Douglass copper processes. For securing the results of the improvement, Mr. Stewart uses a special apparatus. A store tank is used for holding the recovered salt solutions, and from this tank the brine is drawn into a wooden pan or barrel, where it is charged with the roasted ore. It is then heated by steam, and the mercury is added. In a few hours the contents are drawn off into a settler tub, which is also of wood. When the mercury and amalgam have sufficiently settled, the contents, consisting of ore and brine, are drawn off into a filter tub. Here the brine is filtered out, and allowed to run through a tub which contains copper, or mercury, or both, to precipitate any silver or gold which may still remain in solution, and thence is pumped into another tub to precipitate any copper which may be in solution, and thence to a pump tub to be raised again to the original supply tub, for use again in fresh charges of ore. Any surplus of brine will overflow from this supply tank to an evaporator for boiling or crystallizing the salt. The ore from the filter tub is shoveled into the waste sluice.

In this way the chlorides and other re-agents contained in the lixivium of one charge of ore are utilized upon the subsequent charges.

A USEFUL BOOK.—We have received from C. G. Crawford, printer and stationer, 49 and 51 Park Place, New York, a copy of Frank Fossett's work on "Colorado, its Gold and Silver mines, Farms and Stocks ranges, and Health and Pleasure resorts." A complete tourists' guide to the Rocky mountains. The perusal of Mr. Fossett's book has afforded us much pleasure, and has proved very interesting on account of the information we have gleaned from its pages. We may say that we have not before been able to obtain desired facts concerning Colorado. Obligated to rely on gleanings from the press and an occasional correspondent our stock of knowledge has been quite meager. But in this enticing volume we find collated everything calculated to satisfy our constant demands for information concerning Colorado. We cheerfully recommend the work, not only to those interested in Colorado, but for general reading.

Concrete.

[Written for the PRESS by HENRY G. HANKS.]

San Francisco is destined to be one of the largest, if not the largest city in the world, her geographical position being such that this is certain. Nothing but a convulsion of nature violent enough to destroy our magnificent harbor, can prevent it. Assuming this to be the case, should we not lay the foundation of the future city as if there were others to follow us: By taking proper care of our harbor, planning a proper sewerage system, seeking a water supply commensurate with the wants of a large city, and by constructing indestructible buildings? What an oversight, that wide winding streets or avenues like those of Edinburgh, were not laid out in the commencement, with narrower side streets breaching from them, instead of our rectangular streets and heavy grades. What a beautiful city San Francisco might have been made. It is too late to correct this mistake, but experience and good judgment may prevent others.

There is no better, or more sensible way to set our idle men to work than to avail ourselves of the wonderful resources which nature has supplied to us with so bountiful a hand. If we could realize the folly of stock gambling and other demoralizing and hazardous pursuits, and settle down to the idea of utilizing the resources we have within ourselves, a new era would dawn on California.

Nothing can be more certain than the fact that we must soon abandon the cheap and temporary manner of building our houses, and substitute stone and brick for the flimsy and shabby redwood we have used for so many years. We cannot afford to rebuild the city three or four times in a century. It has been absurdly maintained by some that San Francisco can never be built like other cities, of fire-proof and indestructible materials, which would imply that it must ever remain a cheap wooden city, as at present.

It may be well to state the objections that have been made to building of stone and brick in California. The physicians say that these buildings are not so healthy as those of wood; that they absorb water from our moisture-laden sea breezes. But with all due deference to their opinions, I believe that they are too hastily taken. If houses are properly built this objection falls to the ground. In this country it is as necessary to paint the outside of a brick or concrete building as it is to paint a wooden one, and costs no more. Marble and other first-class building stones do not absorb moisture, and then the device of building the walls double may be adopted, which will effectually remove this objection. But do what we may, we shall soon be driven to the necessity of seeking some other building material, as the redwood forests are being rapidly exhausted.

Another objection not so easily disposed of, is the fear of earthquakes, for they are still to be dreaded. Yet, while badly constructed walls are easily destroyed, well-built masonry may be rolled over like an iron safe without being broken. Valparaiso and Naples are instances of well-built cities, often called upon to withstand earthquake shocks. Other objections have been offered, but they are of so trivial a nature as not to be worth mentioning.

Although stone, brick and iron cannot be dispensed with in building a great city, yet some cheaper and more convenient material is sometimes desirable.

It often becomes necessary on billides to erect heavy walls to protect the elevated banks of earth left standing by our senseless system of grades. Nothing is better suited for this purpose than well-prepared concrete; while for cesspools, cisterns, cellars, foundations, garden-walks, etc., nothing could be better adapted, while hard-burned clay sewer pipe supply the want of a cheap and convenient way of obtaining perfect sewerage, and perfect sewerage insures a healthy city. Too much cannot be said in favor of this system.

I have read with pleasure an article in a late issue of the MINING PRESS, on "Concrete as a Substitute for Stone in California." The writer, although he has given a good idea of the importance of the matter, has not fully stated it.

The French word, "beton," has the same significance as the English word "concrete." Common beton is an artificial conglomerate of sand, pebbles, broken stones, and lime.

Beton Coignet, named after the inventor, Francois Coignet, of Paris, is an artificial concrete stone, which is made of an intimate mixture of lime, sand and water, which must be properly proportioned, or the result will not excel common mortar—which it really is in composition. The theory of the hardening of mortar is too well known to require mention here. An excess of lime makes it friable; while an excess of water produces a similar result. It is well known that sandstone consists of sand held together by small quantities of cementing substances, such as carbonate of lime, oxide of iron, etc. In preparing Beton Coignet, sandstone is imitated as nearly as possible, by aiming to have only lime enough to coat the grains of sand and leave no excess. When the hydrate of lime absorbs carbonic acid from the atmosphere, and becomes carbonate of lime, an artificial sandstone is formed, which experience has shown, is equal in many respects to the natural stone. It has been found that the character of the stone

varies with the nature of the lime employed. Common limes, which is pure carbonate of lime, or calcite, rendered caustic by heating strongly in a lime kiln, by which the carbonic acid is driven out, sets slowly, and a long time is required for the chemical changes to take place which have been mentioned. Hydraulic limes sets quicker; and cement still more so.

Hydraulic limes are variable in their composition, but they may be divided into two classes—those containing, besides carbonate of lime, fine silicious sand, and for that reason called "silicious limes"—and those containing from 8% to 18% of clay, and called "aluminous limes". When containing from 18% to 36% of clay and a certain quantity of magnesia, they are called cements.

As the cements vary in character, and as much judgment is required in properly burning them, they cannot always be depended on; some of the best are made artificially, by adding the proper proportion of clay and other substances to the lime, and burning them together. The natural cements are unreliable unless they are carefully selected and properly burned.

When beton is mixed ready for use, it is only slightly moist, and appears like damp sand—it is handled in boxes or wheels in barrows, and when laid in place is tamped with pestles of iron weighing 15 lbs. and upward.

On a large scale, mixing cylinders driven by steam power are used, and belts with buckets on the plan of an elevator are employed to convey the concrete to the mixing cylinder. On a small scale it may be mixed with a hoe on a surface of boards.

Lime for common mortar should be slacked at least 24 hours before used; but for "Beton Coignet" it should be slacked but two hours before required for mixing, and only water sufficient added to cause it to fall to a powder.

A general rule for compounding Beton Coignet may be thus stated:—

Sand—Four to five parts by measure.

Lime—Common or hydraulic, one part by measure.

Cement—One-quarter or two-thirds of one part by measure.

Water—A sufficient quantity.

The exact proportions vary in accordance with the quality of the ingredients and the requirements of the concrete.

For the construction of the walls of common buildings, cellars, foundations, etc., where great strength is not required, a mixture of five parts of sand, one part of lime, and the usual quantity of water is used.

For arches, vaults, cesspools, etc., requiring more strength, the following mixture is used: four parts of sand, one of lime, and one-half part of Portland cement.

For heavy walls to support embankments the same composition is employed, but the wall is so constructed, by being built into the bank, as to support its weight.

For digging cellar floors, sidewalks, etc., five parts of sand, one part of lime, and one part of cement may be used.

For foundations for heavy machinery the following mixture is recommended: sand, five parts; lime, one part; cement, one-fourth of one part.

Many miles of the main sewers of Paris are constructed of concrete, and are found to be quite equal to those of stone masonry, and very much more economical. The following proportions are used:

175 cubic feet of sand.
35 cubic yards of hydraulic lime.
550 lbs. of heavy Paris cement, equivalent to Portland cement.

The ingredients are mixed by machinery on a large scale.

Concrete may either be molded into blocks and laid in mortar like common stone, or built up in a succession of layers making the wall solid or "monolithic," as called in France. For this purpose a crib of boards is made which is movable, the sides are separated from each other the width of the intended wall, and held in place by iron rods which pass through the wall and are afterwards drawn out. The loose concrete is shoveled in and tamped. It is allowed to remain until the concrete sets, when the sides of the crib are taken down and shifted upwards for another course.

One of the advantages in the use of concrete is that skilled labor is not essential to its use. Suppose that some house owner desires to construct a cesspool, and wishes to do it himself at odd spells when he can spare the time, he has only to have a circular frame made the size of the interior of the intended structure. It is imperative that it shall be so constructed that it can be taken to pieces from the inside, and it need only be a foot or 18 inches high. Thus provided, and with materials and conveniences for mixing, a circular hole is dug the required depth and wider than the circular mold by the thickness of the required wall. As the whole structure will be under the ground the outer surface of the wall may be disregarded. The mold is set in place and the outer space filled up with concrete, tamped thoroughly and allowed to set. The boards are then removed and the circular space within the wall filled up to the level of the course, the mold is again adjusted and a second course of concrete laid. This is continued until the surface of the ground is reached; it is then only necessary to dig out the earth again, which has acted as a scaffold, and the work is finished. It may then be covered and put to immediate use. In the same way garden walks, parapets to support terraces, steps, etc., may be made.

An aqueduct which supplies the city

of Paris with water is partly constructed of Beton Coignet. In the forest of Fontainebleau are three miles of arches some of them 50 feet high, the whole is built of concrete including the pipes and arches.

A Gothic church, with spire 130 feet high, near Paris, is built wholly of concrete.

At Port Said, the northern entrance of the Suez canal, the lighthouses and the jetties are all of beton. Twenty-five thousand blocks of beton were laid, each of which weighed twenty-five tons.

At the harbor of Algiers in Africa, the French have constructed enormous works of concrete. The harbor was first laid in large blocks of natural stone, but it was found that the action of the waves was so great that the walls were washed away. It was calculated that blocks of sufficient weight to withstand the waves during heavy storms would require a volume equal to 353 cubic yards. To quarry and transport these

Fig. 1. CAVALIERI'S SEISMOMETER.

blocks to the harbor mouth would entail enormous expense, and the experiment of substituting blocks of concrete was tried, and they were found to be fully equal to the emergency. The entire work was finished in five years, at an expense of \$420,000.

It will be seen that there are many ways that concrete may be utilized; and if the California cement is what your correspondent represents it to be, the materials can be cheaply and abundantly supplied, and it is to be hoped that your readers will avail themselves of the advantages this system offers.

ICE MAKING IN SACRAMENTO.—The Sacramento Times has the following note on a local enterprise. A visit to the premises of Coles

Fig. 5. Angles of Emergence.

Brothers, on K street above Tenth, shows a steady and substantial progress towards completion of their machine for supplying this city with ice. The Pictet ice machine is based on an entirely different principle to that employed by other manufacturers, and it is claimed that ice can be produced more rapidly and at less cost than by any other system. The air of stability that pervades all the operations of the Coles Brothers, indicate that they mean business and have come to stay. They do not intend to sell out, and pledge themselves to supply ice to consumers for at least one cent per pound less than the present rates, an item that will be of some consequence to buyers. An interesting trial of the machine will shortly be had in one of the Comstock mines, for the purpose of applying the principle to the cooling of the lower levels, and doing away with the expensive and inadequate machinery now in use. If the experiments prove successful—and they claim they can cool the mines to an ordinary temperature—there will be "millions in it."

CALIFORNIA SALTED HERRING.—Another illustration of the infinite variety of material in California, for the practice of nearly all the industries known to a world of workers, may be found in the production of salted and smoked herring around Monterey bay. The Monterey Democrat has been given a sample by John Parker, and the editor pronounces them excellent eating, reminding him in flavor and consistency of the famous Dutch herring. Millions of these fish enter Monterey bay every year, their shoals being measured by thousands of yards on the surface and swimming 16 or 20 feet deep, close as the fish can manoeuvre their bodies. They might be the source of inexhaustible wealth, if salted or smoked, as on the coasts of northern Europe.

THERE are 900 tons of standard silver dollars stored in the Treasury at Washington.

Measurement of Earthquakes.

In a series of recent articles in the PRESS upon the subject of earthquakes, we briefly alluded to the fact that by proper appliances, the depth, direction and intensity of the earthquake waves, or trembling sensation experienced by the shock, could be measured. Our attention has been called to a variety of instruments for the purpose, which appear in Prof. Le Conte's geology, an excellent work published by D. Appleton & Co., of New York City. In spite of the many opinions that have been expressed concerning the interior condition of the earth and the causes that seem to engender a continual vibration of some part of the earth's crust, there is still great obscurity hanging about the

Fig. 2.

subject. There can be no doubt, however, that in the phenomena of earthquakes, there exists means of solving many problems which now seem beyond the reach of science. The depth of the origin of earthquakes, which, as we remarked in a former article, probably arises from an explosion of some pent-up force or power producing air explosion, is a material point in solving the problem of volcanoes. The point at which the explosion, which produces the earthquake occurs, is sought to be determined by means of an instrument termed a seismometer, or "earthquake measure." There are many forms of instruments for this purpose, the two most important of which we shall here mention. An excellent instrument for recording slight tremors is one invented and used by Prof. Palmieri, of the Vesuvius observatory. It con-

Fig. 3. Diagram of Vibration.

sists of a telegraphic apparatus with the usual paper-slip and stile. The paper-slip, accurately divided into hours, minutes, and seconds, travels at a uniform rate by means of clock-work. The battery-circuit is closed and opened, and the recording stile worked by the shaking of a metallic bob, hung by a delicate spiral spring above a mercury-cup; the shaking of the bob being determined by the tremor of the earth. Such an instrument records the exact moment of occurrence of earthquake shocks, however slight; also, the moment of passage of

Fig. 4. Co-seismal Lines.

every wave and its time of oscillation; and if there be more than one such instrument, the moment of occurrence at different places gives the velocity of the surface wave, v . It records, however, rather than measures earthquake phenomena; it is a seismograph rather than a seismometer.

The best form of seismometer which we have seen described—that which gives the most important information—is that of Prof. Cavalleri, of Monza. It consists essentially of two pendulums, one horizontally and the other vertically

oscillating (Figs. 1 and 2). The former is an ordinary pendulum, with a heavy bob, b , aimed with a stile which touches a bed of sand, $s s$. The sharp point of the stile rests loosely in a slight depression in a small flat cylinder or button, c , resting lightly on the top of the firm column, d . When the earthquake-shock arrives, the whole building, and therefore the attachment, a , above, and the bed of sand, $s s$, on the floor, will move in the direction of the shock. This direction will generally be partly horizontal and partly vertical. We will consider now only the horizontal element. The pendulum, b , will tend to retain its position, and the bed of sand will move beneath it, first in one direction and then in the other, and the stile will thus mark the sand back and forth to a distance equal to the back-and-forth motion of the earth. The direction from which the impulse came is determined by the side on which the little cylinder falls. It is easy to connect the pendulum with a clock set at 12, in such wise that the motion of the former will instantly set going the latter. The difference between this clock time and the real time will give the instant of transit. It is clear that this pendulum does not give the whole amount of the vibration or motion of the shock, but only the horizontal element. If $a b$ (Fig. 2) represent the direction and amount of vibration, then $a c$ is the horizontal element measured by the pendulum. This instrument, therefore, gives the moment of transit, the direction of transit, and the horizontal element of vibration.

The vertical element, $b c$, of the vibration is given by a vertically oscillating pendulum (Fig. 2), the point of which rests lightly on our arm, a , of a very easily-moved lever, the other arm, b , of which acts as an index by means of a graduated quadrant. When the shock moves the floor of the building upward, the heavy weight of the pendulum retaining its position by stretching of the wire spring, the arm b is pressed against the stile, and the arm b is elevated; when the floor descends again, b is retained in its elevated position by a ratchet at c , and thus records the amount of elevation of the floor. This pendulum, therefore, gives the upward movement or one-half the whole vertical element. Having now the horizontal and vertical element, $i. e.$, the base and perpendicular of a right-angled triangle, the hypotenuse, or whole oscillation, and the direction of oscillation, or angle of emergence (a, Fig. 3), are gotten by simple calculation, or by accurate plotting.

The important facts recorded by this instrument are: 1. The instant of transit; 2. The direction of transit; 3. The direction of oscillation, or angle of emergence; 4. The amount of oscillation. From these elements (if we have several seismometers scattered about the country) may be calculated: 1. The velocity of transit; 2. The position of the focus; 3. The form of the focus, whether point or fissure; 4. The force of the original concussion. The most important of these are the position and depth of the focus.

It must be borne in mind that the trembling of the earth is the result of a shock occurring somewhere in the interior of the earth, which causes a vibration of the earth's surface in waves similar to the action of water when its surface is disturbed. Now these vibrations, which are termed earthquake waves, begin at the point of the explosion and spread with greater or less rapidity, according to the geological nature of the strata, until they strike the surface of the earth at a point nearest the explosion point, whence they extend over the surface of the earth in different directions. The point at which the wave first strikes the surface of the earth is called the "epicentrum," and to find this point is to locate as near as can be the origin of the earthquake, by means of the seismometer the direction of transit of the surface-wave. If, by the use of many such seismometers, or even by rougher methods, we get a number of these surface-lines of transit, by following these back we get the epicentrum at their intersection. Or if, by means of many seismographs giving time of transit, or even by observatories or stations of any kind with accurate clocks, we get several points of simultaneous arrival of the wave, then by drawing a curve through these points we have a coseismal curve. A perpendicular drawn from the middle point of the line joining any two of these points will pass through the epicentrum, and two such perpendiculars would determine its position. Fig. 4 represents coseismal curves, and b, c, d , three points on the curve; a is the epicentrum.

The spherical wave is a wave of longitudinal oscillation. The direction of oscillation, therefore, is the same as the direction of transmission (wave-path), which is the radius of the agitated sphere. If, therefore, the direction of the ground-motion (the line $a b$, Fig. 3) be followed into the earth, it carries us back along the wave-path to its origin, the focus. Two such wave-paths by their intersection would determine its position. Thus, in Fig. 5, if c and b be the position of two seismometric observatories, the angles of emergence, $a c a$ and $a b a$, being given by observation, and the distance, $c b$, being known, we have all the elements necessary to determine either by calculation or by accurate plotting the wave-paths $c a$ and $b a$, and their point of intersection a , and therefore of the depth $a z$.

Although seismometers, such as we have described, are necessary for accurate results from few observations, yet by multiplying the observations, even by rough methods, approximative results may be obtained.

DEWEY & CO.**American & Foreign Patent Agents,**

OFFICE, 202 SANSOME ST., N.E. COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 202 Sansome St., N. E. corner Pine, S. F.

PATENT**LIFE-SAVING RESPIRATOR****Prevents Lead Poisoning and Salivation.**

INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Mines, Guano Works, White Lead Corroding, Feeding Threshing Machines and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price \$3 each, or \$30 per dozen. Sent post-paid to any address upon receipt of price.

SETH MARSHALL, Jr., Agent,

309 California Street, San Francisco, Cal.

Send for Descriptive Circulars containing testimonials of well-known parties who are at present using them.

**SAVE YOUR GOLD!****Highly Important to Miners and Quartz Mill Men!****SILVER PLATED AMALGAMATING PLATES.**

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated. With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

Nos. 653 and 655 Mission Street, San Francisco, Cal.

EDWARD G. DENNISTON, PROPRIETOR.**THE ELKINS****"BOSS" GOLD AMALGAMATOR.****Is the Best, Simplest and Cheapest Amalgamator in Use.**

Nothing about it to get out of order or wear out. Weighs only 500 lbs.—heaviest piece weighs 100 lbs. Is automatic in its working. Measures, feeds, screens and passes all material through a large body of quicksilver; then washes and cleans without care or attention. Requires no more power than a large grindstone. Uses water over and over again where water is scarce. All water required can pass through a 3-inch pipe. Capacity, two to four tons per hour. Saves 90% of precious metals. Price, \$250. Pump \$25 extra. Send for circular.

ELKINS & LYNCH,

No. 318 Pine Street, - - SAN FRANCISCO.

**BUTTS'**

IMPROVED ANTISEPTIC "CHALLENGE"

Fruit, Vegetable and Hop Drier AND CANNING APPARATUS.

The cheapest, quickest and greatest labor-saving Drier ever introduced. Retains the quality, color and flavor of the fruit. The Canning Apparatus has a capacity of from 500 to 4,000 cans per day. Machines varying from 500 lbs. to 10 tons capacity per day constantly on hand. For Circulars, prices, etc., address

A CARD.**To Parties Interested in Mining and Milling.**

Call at J. HENDY'S, N. E. corner of Mission and Fremont Streets, San Francisco, and examine COLEMAN'S PATENT SLUICE. It will save both float and flour Gold. The best system yet devised. No power required to work it. Examine it and judge for yourselves before purchasing elsewhere.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

C. C. Bitner's Apparatus for Obtaining Metallic Copper from its Solutions.

Patented March 18th, 1873. Will precipitate with steam in three hours, requiring no machinery to run it. Cost of constructing apparatus, \$75. The old cylinder process takes four hours to precipitate and costs from \$1,200 to \$1,500 to construct, besides the machinery to run it. For right to use my Precipitator address O. O. BITNER, Spenceville, Nevada County, California.

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

To Gold Miners!**GREAT IMPROVEMENT**

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

AN ENGINEER,

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draftsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office.

Ingersoll Rock Drills.

In use in the largest and best
Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-thubbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

RUSSELL'S AMALGAMATOR.

Patented June 25th, 1878.

SAVE YOUR GOLD And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crose and Blackwell, London, &c., &c.; and by Grocers and Oilmen throughout the World.

Machinery.

GOLD AND SILVER Grinding and Amalgamating MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chlorinating Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

SPERRY'S Wrought-Iron Frame FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc. Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,250.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Grinding Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

COLORADO.

ITEMS.—Exchanges to date: Senator Jones asserts that the deepest mine in Leadville is down only 120 feet. The mineral deposits lie flat and are of immense size. Many fortunes have been made there, and the Senator says it is the best place for a poor man to prospect in, with more chances of striking mineral than in any other district. In fact, all the chances are in favor of striking ore by digging, and when once struck there is no trouble in extracting it. The city at present contains about 30,000 people and is still growing. A run from the Horn Silver mine, in the Eagle River country, makes a showing of 1,611 ounces. The Tribe of Assa mine, on Iowa gulch, assays 96 ounces. Jay G. Kelley found gold-bearing quartz near the city that assays \$4,000 to the ton. Further particulars cannot be given. A washing from a single pan from the Mount Pleasant placer, at the head of Iowa gulch, shook yesterday yielded nine cents in gold.

FAIRPLAY, Park Co.—*Tribune*, Sept. 3: Last week the Sacramento mining company of the district of that name shipped 19 tons of high-grade ore, running from 250 to 400 ounces silver to the ton.

ALMA.—The shaft in the Fanfrie Barrett mine is now 4 ft deep, and as ore was encountered 9 ft from the surface there is now a body of ore exposed 33 ft in thickness. The Mount King mine has a fine body of ore running from \$200 to \$500 per ton in silver. The property is 2½ or 3 miles from town. One thousand or more men are prospecting here, some of them within a few hundred feet from the town. Some ore was brought down from the Truman mine, at the head of Mosquito gulch, that assays \$3,410 ounces silver per ton. The Grace mine adjoining is doing out-top and is shipping high-grade ore. One piece of float ore, in the form of a boulder, was found in the timber near the edge of town, that when broken up and brought to the sampling works fetched \$25. The Russia mine on Mount Lincoln is taking out considerable ore, the select runs about 1,570 ounces per ton. This has been a steady producing mine for several years. Some rich specimens have been brought in from Mount Silver, found in the float. This district is producing considerable silver.

SILVER CLIFF.—*Prospector*, Sept. 1: The Wet Mountain mining and improvement company have five mines, with good prospects, showing true fissure veins, two or more of which they contemplate working for depth. Thus far their lodes have shown good mineral, both in gold and silver. The Red Rock is now showing mineral quartz, the finest that has yet been discovered. The Silver King has thus far proved very rich. The Humboldt has been opened richly, while the Terrible bids fair to prove a grandly rich paying mine. Following these comes the news from Gibson gulch, 11 miles east, in Verde district, of the discovery of silver, gray copper and free gold in great abundance. The specimens from the Gibson lode, the Uncas, were extremely rich, showing ruby silver and free gold in goodly quantities. The Uncas is but 17 ft down, yet its owner informed us that he had a good pay-streak and five tons of rich ore on the dump.

IDAHO.

ITEMS.—*World*, Sept. 2: The mines on Wood river at Yankee Fork are not narrow as was first thought. They widen in depth and are very rich. Several rich discoveries have been made in the Saw-Tooth range. A clean-up has just been made from 81 tons of ore from the Ebenezer mine at the Gold Hill mill. The yield was \$6,375, or over \$78 per ton. The fineness of the gold was 876.

MONTANA.

ITEMS.—*Butte Miner*: In Missoula county a placer claim of 100 acres has been located on Front creek near Cedar. The creek is 30 miles long and claimed to be very rich in gold. The Alexandra, a new claim 350 ft south of the Lexington mine, has been opened, it shows at the surface a three-foot heavy gold ore, which is expected to improve with depth. It pitches to the south, with a grade similar to the Lexington. A rich strike has been made in the Alder gulch near Virginia City. At the head of Alder gulch the country rock is slate. Further down the creek it is granite, and it is right on the line of junction of the two different formations, the granite and slate, that the new lode has been discovered. The ledge is about 100 ft in width, bearing gold in every portion, no part of it yielding less than \$12 per ton. The first-class ore is found in a vein 16 ft wide, which averages a little over \$100 per ton. The quartz is very soft, so soft that it can be panned or washed in sluice boxes and a very considerable proportion of its treasure saved by that primitive process. In Hungry Hollow, a tributary of Alder, a rich gold lode has been discovered. Mr. H. Gray, who has been working in that region very actively. The miners down the gulch are doing exceedingly well this season. The fume of E. F. Bond, especially will yield a rich harvest of dust. A good deal of the work done this season has been done on heretofore unworked ground.

NEW MEXICO.

GRANT COUNTY.—*Herald*, Aug. 30: A dozen mines are being worked at Hillsborough. The "Wexen" mine is a true fissure vein, and ore is better at 50 ft. Assays from bottom of main shaft give five ounces of gold per ton. Twenty men are at work, taking out about 1½ tons each per day. The King mine is yielding rich returns. A recent run of ore exhibited \$124 per ton. The mill is running on full time with plenty of ore. Several mines are being developed at Shakespeare.

GENERAL ITEMS.—A party of prospectors have struck some silver leads near the head of the Vermejo. At Georgetown rich ore is being taken from the "Commerical" and McGregor mines. In the former are several streaks of high-grade ore. Both horn and native silver exist in large quantities. In the "McClure" mine considerable high-grade ore is taken out. Many miners are prospecting in the Black Range, east of Georgetown. Some large ledges have been found showing metal. Meredith & Aiman are concentrating the ore from two years' tailings at their mill. They are getting about 200 lbs of good metal from each ton of tailings, which will probably assay high. The ore which they are now extracting may be called the sulphide of silver, although it contains a good deal of chloride.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Alexander, Sept. 4th, \$3,779; Hillside, Sept. 5th, \$4,100; Hillside, Sept. 8th, \$4,300; Ophir, Sept. 6th, \$25,767.97; Northern Belle, Sept. 3d, \$2,870.19; Con. Virginia, Sept. 2d, \$52,669.03; California, Sept. 6th, \$54,029.52; Grand Prize, Sept. 8th, \$13,000; Belle Isle, Sept. 8th, \$25,000; Martin White, Sept. 3d, \$3,462.21; Bodie Con., Sept. 9th, \$24,500; Northern Belle, Sept. 6th, \$4,696.01; Tiger, Sept. 9th, \$18,000.

In San Francisco half dollars are quoted at 99½ selling; 99½ selling; trade dollars, 97 buying, 98 selling; Mexican dollars, 98 buying, 98½ selling.

Of the ten-dollar refunding certificates, the Treasury Department has sold \$40,012,750.

Mining Decisions.

In the case of the Adelaide Consolidated Silver Mining and Smelting Co. vs. Gallagher and others, it appears that the defendants made application for a patent for the Camp Bird mining claim, entry No. 130 of survey No. 237, in the California Mining District, Fairplay Land District, Colorado. By the survey the claim is represented as a parallelogram, 1,500 feet in length by 300 feet in width. The survey of the lode in the claim crosses the "Adelaide Lode" at nearly right angles, and the amount of surface ground contained within the Adelaide claim at the point of intersection is 2,972 acres. The preliminary proceedings were in strict conformity with the requirements of the mining law, and no adverse claim was filed or suit commenced during the period of publication. The Gallaghers afterwards made entry of 7,305 acres of surface ground of said mining claim, being the exact amount of land contained in the survey thereof after deducting the surface ground contained in the Adelaide claim at the point of intersection. This amount of land appeared in the published notice of the application for a patent. The Adelaide Co., however, filed a protest in the land office claiming that by the description in the official survey it would appear that the Camp Bird Co. intended to take the land at the point of intersection of the two claims, and among other things asked that a clause be inserted in the patent issued on the Camp Bird claim excepting and excluding the area in conflict with the Adelaide claim. The Camp Bird Co. disclaimed any interference with the surface of the Adelaide claim, and admitted the priority thereof, but claimed that such a reservation in the patent would be unusual.

The land office, however, decided to approve the Camp Bird application and to issue a patent thereon with an excepting clause, which excepted and excluded from "this conveyance all surface ground contained in the Adelaide location, as shown by the foregoing description, together with all veins, lodes and ledges lying and being therein, to which the said Adelaide mining claim is entitled by reason of its said location." Both parties appealed from this decision.

Secretary Schurz, in his decision, among other things, says: "The only law relating to cross lodes is found in Section 2336 of the Revised Statutes, and is in these words: Where two or more veins intersect or cross each other, priority of title shall govern, and such prior location shall be entitled to all ore or mineral contained within the space of intersection; but the subsequent location shall have the right of way through the space of intersection for the purposes of the convenient working of the mine. And where two or more veins unite, the oldest or prior location shall take the vein below the point of union, including all the space of intersection."

"Under this statute the right of the parties are made to depend upon the fact of actual intersection of the veins, and priority of location; matter which it is the peculiar province of the judicial tribunals to determine; yet, in cases where mining locations cross each other, and there is reason to believe that a contest may arise in future, the rights of neither of the parties in interest should be prejudiced prior to a judicial determination thereof, by the insertion of unnecessary habendum or reddendum clauses in the patent."

"In this case the Camp Bird Co. has not entered, and is not asking for a patent for the surface ground embraced in the Adelaide claim at the point of intersection of the two claims, yet its vein may extend through the ground belonging to the Adelaide and still not intersect with the Adelaide vein. In that event, the right of the Camp Bird owners to pursue said vein through the ground of the Adelaide at the point of intersection of the two claims is vested by law, and ought not to be limited by the patent; while on the other hand, the right of the owners of the Adelaide to pursue their vein is equally well protected by the statute, and should not be prejudiced by the grant to the Camp Bird Co. Under the circumstances of the case, the only way by which the interests of both parties can be fully protected is by making the excepting clause in favor of the Adelaide Co. as broad as the granting clause to the Camp Bird Co.; for, by so doing, both will receive all that the law gives them, and neither will have any legal advantage."

Mr. Schurz, prescribing a form which would in his opinion best protect the interests of the parties, adds this proviso: "Provided, That nothing contained in this grant is intended to interfere with the legal rights of said claimants in case said veins are found on exploration to intersect with each other," which was ordered to be inserted in the patent, so as to make the excepting clause as broad as the granting clause therein.

In the case of the Iowa Mining Co. vs. Bonanza Mining Co., on appeal from the land office, Secretary Schurz held:

"1. A failure on the part of an adverse claimant to prosecute his suit to judgment with reasonable diligence shall be a waiver of his claim."

"2. The question of diligence in the prosecuting of a pending suit is as much a question for the determination of the court as any other

question of law or fact which may arise in the progress of the case, and one which, after this court has acquired jurisdiction, should be left for its determination."

The case involved a controversy about certain mineral lands in the Virginia Mining District, Carson City Land District, Nevada. The plaintiff had commenced suit on its adverse claim in the District Court for the First Judicial District of Nevada, but had not taken any steps to prosecute its suit. The land office decided that the Iowa Co. had waived its adverse claim by a failure to prosecute said suit with reasonable diligence, and that the Bonanza Co. was entitled to a patent for the land on fully complying with the requirements of the mining law. Secretary Schurz decided that the Nevada court had acquired jurisdiction over the cause, and that the land office had no power to interfere with matters which this court alone should determine, and hence, although the lack of diligence was a waiver of the claim, the court in which proceedings were pending could alone determine whether there had been such a waiver. The decision was therefore reversed, without prejudice to the rights of either party, and further proceedings stayed to await the result of said suit.

The Mechanics' Fair.

The following are some among the most interesting exhibits in the fair:

The Union Iron Works.

The Union Iron Works (Prescott, Scott & Co.) make an exhibit of some few of the engines, hoists, etc., which they have on hand, but, of course, cannot display any of the heavy mining machinery which is a specialty of the establishment. They show a few of the articles, however, which they make, among others, vertical, horizontal, compound and marine engines, direct acting, hoisting and pumping machinery, steam pumps, a quartz mill, etc. We have described the Bruckner mill, displayed in this exhibit. Another feature of interest is the Waterhouse & Brewer engine, a little machine of very simple construction, which can be used either single or compound. This engine is intended for small power, and is so made that it can be sold at remarkably low prices, as compared with those of ordinary construction. Prescott, Scott & Co. have taken hold of the engine with a view of introducing it in places where a small and single power is required.

The firm are well known in the community, the foundry being the largest in the city. Mr. Irving M. Scott, one of the firm, is President of the Mechanics' Institute. The works have been running many years, and build steam, air, and hydraulic machinery of all kinds. They are provided with all the largest and most improved tools in the business, and the shops are the most completely outfitted of any in the State.

Kortick's Safety Hook.

Mr. Frank Kortick exhibits a peculiar safety hook, which he recently patented through the MINING AND SCIENTIFIC PRESS Agency, which is intended more particularly for use in connection with the bits on harness, or as an attachment of the whistle-tree, by which tugs may be connected with them. The device consists in the employment of a hook having a slotted shank which receives the link, the hook being pivoted, so that its center of motion in the center of the circular head of the connecting bar and the point of the hook lies so near the edge of this disk that it prevents the link or ring from being removed, unless the hook is turned to a point where a semi-circular notch is formed in the head, so that the ring may drop into this notch, and allow the hook to swing past it, when it may be removed; at all other times it will be securely locked in place. The advantages are the simple method by which the connection is made or unmade, and the impossibility of unlocking it except when desired.

Overend's Feed Water Heater and Pump.

In the model case of Dewey & Co.'s MINING AND SCIENTIFIC PRESS Patent Agency exhibit at the fair, is shown a model of a feed water heater and pump, patented some time since by John A. T. Overend of this city, and in use in a number of places here. It is a simple, cheap and durable heater, condenser and pump combined, requiring but very little power to operate it, and saving a large per cent of fuel and water by mingling the exhaust steam from engines directly with the cold feed water, thereby heating the feed water and condensing the exhaust steam, and forcing, with a pump, into the boiler a sufficient quantity of water thus obtained to supply it at about 212 degrees of heat. This pump can be used separate from the condensing chamber and heater, if desired, for pumping cold water or liquids; or it may be used as a hand pump as well as by power. One of these pumps may be seen at work at Mr. Overend's, No. 506 Commercial street.

Miller's Pressure Blower.

Mr. Morgan B. Miller has connected, so as to be shown running, one of his improved fans or pressure blowers, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency. The blades of the fans are made in a peculiar shape, so as to utilize all the surface,

and around the periphery of the fan box is a pressure chamber, into which the air is forced and compressed by the fan, and from which it is led off by discharge pipes. This fan is very easily run, and really compresses the air so effectively as to give a much greater volume of air than ordinary blowers of twice the size.

News in Brief.

HEAVY, continuous rains prevail on the Island of Cuba.

THE Mechanics' fair opens at Portland, Or., October 15th.

THE yield of crops in Idaho this season is unprecedented.

THE weavers at Fall River, Mass., have voted not to strike.

WORK has been commenced on the Nevada Central railway.

THE Governor-General of Canada arrived at Toronto, Sept. 9th.

EIGHTEEN deep-water ships arrived in San Francisco Sept. 9th.

A DAMAGING drouth prevails in the provinces of Chekiang, China.

A SEVERE frost has caused immense injury to the coffee crops in Brazil.

THE steamer *Bengal*, from Montreal for London, grain laden, is ashore.

DURING August 1,638 carloads of grain were landed at South Vallejo.

A MINISTER was beaten to death Sept. 9th at Zaleski, O., by his son-in-law.

THE inhabitants of Novi-Bazar have determined to resist Austrian occupation.

SIX miners were suffocated in a mine at Alta, Utah, last Saturday by poisoned air.

THE Memphis Odd Fellows appeal to the Brotherhood at large for material aid.

BLORE, formerly architect to Buckingham Palace and Westminster Abbey, is dead.

EIGHTY-FOUR young persons have left Moscow under sentence of hard labor in Siberia.

SILVER in London, 51½d, consols, 97 11-16; 5% U. S. bonds, 105½; 4s, 105; 4½s, 108½.

IT is believed in Madrid that King Alfonso's marriage will be celebrated in December.

THE Indians have deposited their chiefs at San Bernardino without causing an outbreak.

ALL the Vancouver Island Indians have gone to Puyallup valley, W. T., to pick hops.

THE surrender of Cornwallis is to be celebrated on the 19th of October at Yorktown.

CROPS in Bulgaria having failed, the government has forbidden the exportation of cereals.

LEONARD, son of Nathaniel Montefiore, of London, died last Saturday at Newport, R. I.

FULLY 1,000 silk operatives have arrived at Paterson, N. J., this year, from foreign lands.

PENNSYLVANIA is nearly clear of tramps, owing to the stringent law and the revival of business.

THE etate of siege has been raised in the Bulgarian districts of Rasgrad, Simla and Osman Bazar.

SEVEN persons were drowned lately by the sinking of a yacht in Henderson bay, New York.

DR. SAMUEL A. FINLEY, ex-Surgeon General U. S. A., died in Philadelphia Sept. 9th, aged 82 years.

HIGH water prevails in St. Petersburg, and violent wind storms have done considerable damage.

AT Liverpool wheat is quoted at 8s 6d@9s 6d for average California white, and 9s 5d@9s 10d for club.

THE Mussulmans in Eastern Roumelia declare that they prefer a Russian to a Roumelian government.

AN insurrection has broken out in Kardistan.

THE Pennsylvania State fair is in progress at Philadelphia.

GENERAL GRANT is to be received in San Francisco, with a general welcome, outside of all party lines.

IT is estimated that about \$100,000,000 will be sent to this country from Europe during the present year.

JAY GOULD tells the Howard Association of Memphis to keep at its noble work and he will foot the bill.

A LARGE force of men are engaged on the work of the locks and canal of the cascades of the Columbia.

A DISPATCH from Paris announces the death of Baron Isadore Taylor, the well-known author and traveler.

THE ship *Frank F. Curling*, from Maine to San Francisco with 2,600 tons of coal, has foundered off Cape Horn.

AN appeal is to be made to the Irish people in all parts of the world, to aid in the creation of a class of peasant proprietors in Ireland.

SERIOUS trouble is reported from Cabul, the British Embassy having been attacked by several Afghan regiments, and the British representatives massacred.

AMERICAN LOCOMOTIVE.—The American locomotive exhibited at the Paris exhibition was recently sent to Milan for trial, having been refused at Florence. Great opposition has been made to it by the Belgian and English makers of locomotives, but in spite of foreign jealousy, it is probable that a trial will be accorded, and it is thought that the prospects are bright for the introduction of American locomotives on Italian railways.

PRESSES AND DIES.—Attention is called to the advertisement of F. A. Robbins, in this issue. Mr. Robbins has been long and well known as a model maker and die sinker, and has earned his reputation by good work.

Treatment by a Purely Scientific and Rational Method Without Drugs of any Kind.

THE TREATMENT DEPARTMENT EMBRACES ALL APPROVED REMEDIAL AGENTS, AS OXYGEN INHALATIONS, VACUUM TREATMENT, THERMO-ELECTRIC, TURCO-AMERICAN, ELECTRO-MAGNETIC, GALVANO-CHEMICAL, STEAM, VAPOR, WARM AIR, AND ALL FORMS OF WATER BATHS;

Swedish Movements, The Health Lift, Splanometer or Lung Strengtheners, all Electric, Galvanic and Surgical Appliances, Sun Baths, and Solar Ray Surgery, new and perfect Truss for the Radical Cure of Hernia, lately discovered Chemical Compound for the speedy, safe, painless and permanent removal of Cancers, Scientific and successful method for the Cure of Fles, etc., etc.

Aims to keep Abreast with, if not in Advance of the Progressive Age.

It has been the mission of this System to mold public sentiment, and this Institution will hope to be no disgrace to the immortal name it has assumed. The time has come when Physicians of this School can afford financially to keep a conscience; in fact it is disastrous financially as well as morally to compromise the truth one iota; hence patients can rest assured that they will be treated by the Physicians after the most approved and scientific methods, out of pure and enlightened selfishness, recognizing the truth and beauty of this great principle: "The Universe is so ordered and arranged that the real and permanent good of every creature is best subserved in promoting the real and permanent good of every other being."

THE BOARDING DEPARTMENT.

The table will be supplied with the best the excelsior market of the world affords, embracing fruits, grains, vegetables, meats, fish, fowl, eggs, cream, etc. Regular and transient boarders will be accommodated as well as patients. Business and professional men and women who are tired of restaurant fare, may appreciate eating to live a more healthful and enjoyable life. Pure food means pure blood. Pure blood means good health.

The vegetarian school has demonstrated beyond the possibility of a doubt that farinaceous dishes, sweet and salt fruits are sufficient to maintain a hard working man in perfect health. Such a diet might certainly be substituted by a sedentary people for the greasy steaks and ragouts. — Popular Science Monthly, December, 1873.

The Rooms are pleasant, warm, well ventilated and sunny; convenient to treatment rooms, so as to afford the best advantage of nursing and professional attendance.

GENERAL PRACTICE.

Fever, and in fact all cases may be treated at home successfully. Parturition, confinement cases are taken in the Institution or attended at home in any part of the city or country. Preparatory treatment in these cases is most important. Testimonials of extraordinary cases and cures can be seen on application. The most desperate cases, and especially those that have been given up as incurable by the old methods, are invited. Puerperal and typhoid fever and diphtheria cases, after all other methods have failed, may be said to be a specialty. Send for the TRALL HEALTH JOURNAL.

VOLUME XXXIX
Number 12

An Improved Pulverizer and Roller.

We illustrate herewith an improved roller and pulverizer, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by George Meding, of this city. The invention is in that class of pulverizers or clod crushers which are rolled over the ground, and by that means break up the lumps and leave the soil in proper condition for sowing seed.

To the frame of the roller is attached a pole for the horses, and in the rear is a seat for the driver, as shown in the engraving. The axle is fixed to the frame and does not revolve.

On the axle is mounted the rollers, which may be made in two parts, with a bar between them for giving center support to the axle. These rollers are formed of four-sided bars, secured in a circle to the edge of the wheels. The bars are so placed that their edges are outward and strike the ground, so as to more effectually cut up the clods or lumps. Rods extend across between the ends of the rollers, inside, for strengthening, and are set up by nuts, so as to keep the crushing bars in position. By unscrewing these rods the wheels may be separated, so that the four-sided bars may be turned and bring new edges outside. When, however, the inside binding rods are screwed up the bars cannot be turned, and their sharp edges are kept in proper position. The pulverizing bars are secured in position in the wheels by square countersunk holes being made in the wheels. As these holes are not made through the wheels the bars cannot move endwise when the binding rods are screwed up, and the shape of the holes in the wheels is such that they cannot rotate.

Rollers made in this manner are much more effective as clod crushers or pulverizers than those of ordinary construction. The sharp edges of the bars cut or break the clods without pressing them into the ground. Such pieces or lumps as pass through the interstices between the bars are rolled over and over again until fine enough to pass out again. When the edges of the bars become dull they can be turned, so that fresh edges are presented. In this way each bar can be turned four times before needing renewal.

Rollers of this kind can be made comparatively light, and be easier on the draft animals than the heavy plank rollers, while at the same time, from their peculiar construction, they are very much more effective than those of ordinary construction. Each pair of wheels for each roller, when there are two, revolves independently on the shaft so as to facilitate turning. The wheels may be made open at the sides as shown, for lightness and facility of construction.

In order to give the roller the best possible effect, and make the edges of the bars last as long as possible, the inventor prefers to make them with concave sides. This produces a thinner, and more cutting and effective edge; and these bars may be rolled as cheaply as any other form by having rolls provided for the purpose. Mr. Meding has had this pulverizer in practical use for some time, and finds it to answer the requirements perfectly. It leaves the ground well pulverized and smooth, ready for seeding.

This roller will work where no other can, except when the soil is too wet. It will crush the clods, even when dry, and in that way enable the farmer to get his summer-fallow ground pulverized; and when used after sowing, will leave the ground smooth, which will save much on his machinery and horses when harvesting is going on. Its use will enable the hay-rake to rake clean, and no clods will be found in the hay. The roller will not only be valuable on atong clay or adobe land, but even on light soil it will prove efficient, since it is heavy, and by putting more weight on it can be made heavier, if desired. The mark this roller leaves after it is something like the marks of a very fine harrow, which is considered, by some, better than a perfectly smooth surface. The rays of the sun will not come perpendicular on the surface. If necessary to break the crust formed after a rain, by rolling over again crossway the earth will be easily pulverized. If the roller is not wanted on it, a comparatively light harrow will

pulverize it by harrowing the same way it is rolled, the harrow coming across the small "combs" and breaking the crust, without working too deep in the ground. Rolled after the field is sowed, these small "combs" will give a kind of protection and lee to the young sprout when it first peeps out on the surface.

The roller can be made of any size or length, if desired. One of them in use is 8 feet long, and the cylinder is 36 inches in diameter, and will weigh over 1,600 pounds. Most of the weight is in the rollers, and nothing else than the driver and the frame is weighing down on the axle, which renders it comparatively light for two horses.

The patent right is for sale, or contracts for making the roller can be obtained by applying to the inventor, George Meding, at Reading, Shasta county, Cal.

MINING INTERESTS IN NEW YORK.—The efforts made in the East to develop the mining business are certainly an indication of the growing importance of mines as an investment. We are hardly prepared to say that mining stocks will usurp the position railroad, coal mine and other stocks have hitherto held in the East, al-

Assessable and Non-assessable Stock.

The New York *Mining Record*, in contrasting the two systems, favors the assessment system of mining stocks. Mining incorporations organized under the laws of Colorado and New York are not legally subject to assessment, while in California and Nevada the assessment plan seems to be regarded as the only practical method. Complaints are loud against the non-assessable stock system, because of its danger to the interests of small investors. There is no doubt that mining, as a rule, requires constant outlay for development, dead work and machinery. This development fund in the non-assessable system is created by the sale of what is known as the working-capital stock, to effect which every effort is made to get out ore enough to enable the managers to declare a dividend. In the case of the Flagstaff mining company, of Utah, reported in a former number of this paper, money was borrowed on the strength of the ore in sight and used in paying dividends. This before any work was done to place the mine on a permanent industrial basis.

This is distasteful to the *Mining Record*, inas-

Oil from Shales.

An important industry has sprung up in Scotland, which is of some practical benefit in this country, where the crude material exists in large quantities. It is the production of naphtha, paraffine and ammonia from shale. As far back as 1848, James Young had a small petroleum spring which was met with in a colliery at Alfreton, in Derbyshire, and when that became exhausted he endeavored to obtain the same oils by distilling coal. After many trials he was fortunate in meeting with what may now be termed the famous Boghead Cannel, so well known for its richness in oil.

Some shale bears a strong affinity to coal, which fact led to a celebrated trial at Edinburgh in 1853, in which the most eminent chemists, mineralogists and geologists could not agree upon the question as to whether shale was coal or not. Some coal, such as that known as "Curly Cannel" peculiar to the Mold district, in North Wales, gives a large percentage of oil, and at one time was extensively distilled. Some other shales are also rich in oil, and at Barnstaple, far away from any coal field, a bed of shale, highly impregnated with oil, was found while digging some foundations. It was found traversing the upper devonian shale, but it is met with most extensively in connection with the coal measures.

The oil is in great demand, and the price is such as to leave a good profit, if we are to judge by the dividends paid by one company and the vast sums made by a few individuals, who have had something like a monopoly of the manufacture since it was first commenced. The value of solid paraffine is considerable, and with respect to it, Liebig, the great chemist, said if anyone succeeded in producing it from coal it would be one of the greatest discoveries of the age. This has been accomplished, and from shale is obtained a white, dry, odorless substance, portable, and capable of being burned in a lamp. Amongst the various works in Scotland nearly 800,000 tons of shale are distilled annually, producing nearly 30,000,000 gallons of crude oil, from which about 12,000,000 gallons of refined oil are obtained, in addition to large quantities of naphtha, solid paraffine, ammonia, and other chemical products.

Our own immense supply of petroleum may not, perhaps, justify the distillation of coal to obtain products which are obtained from petroleum. Every refinery turns out enormous quantities of paraffine, both hard and soft, which is easily and cheaply refined by the Byerley process, one refinery in Cleveland, Ohio, alone turning out from 12 to 20 tons of solid paraffine per day, about 3 tons of which is soft and used for chewing gum. The oil from shales is both colorless and without odor, and this alone may be an inducement. The expense of refining petroleum oil is considerable, notwithstanding its enormous quantity, and it requires considerable handling. Whether the distillation of coal would enable us to obtain a cheaper product is possible, for we are now paying more for a gallon of refined oil than for a barrel of crude. Coming into use largely for cooking, we need a cheap, odorless oil. Our resources on this coast, in the way of oil productions, are large, and we certainly ought to be independent of the tin cans sent us from the East at a high price.

TUCSON NOTES.—Capt. W. H. Seamane informs us that the city of Tucson has now a population of some seven or eight thousand, three-fourths of whom are Mexicans. A large increase is expected as soon as the weather becomes cooler. Tombstone is a very active camp, and is rapidly increasing in population. Some persons claim that a large town will grow up there, but it is predicted that the "hoss" town will be located near the San Pedro river, fifty or sixty miles east of Tucson, where the S. P. R. R. will cross that stream. The advent of the locomotive is expected before the first of December next.

CONNECTION has been made between the Union and Sierra Nevada mines.

MEDING'S IMPROVED ROLLER AND PULVERIZER.

though the former are gaining ground daily. There is something more solid and substantial about a paying gold or silver mine, and the fluctuations of value are less than in any other investment. It is now proposed to establish a miner's bank at New York, which will advance money on good prospective or dividend-paying mining stocks at nine per cent., and to secure the same facilities and ease of trading in mining stocks as can be got on railroad and other securities listed at the N. Y. Stock Exchange. It is claimed that no speculation of any account in mining stocks can be looked for until this advantage is offered the public.

CALIFORNIA MINING NEWS.—We are in receipt of inquiries concerning the development of the mineral resources of our State of a more detailed character than we can gather from some of our exchanges. Indeed, we are obliged to rely for news from many localities upon correspondents. We would be glad to receive reports from every county, and solicit from all reliable facts about the mining business, which at the present time is being so rapidly developed. New discoveries are being made, and new methods tried. We desire to afford scope in our columns for whatever information may be of interest to the readers of a mining and scientific journal. Let all who are interested in removing the imputation of California mines being exhausted write us, and we will give due credit.

much as foreclosure is generally a speedy result, sacrificing the most of the stockholders, and says a good word for our system by advising its readers that, "under every aspect we must regard the system of assessable shares the safest for investors, and the other system as fraught with hazard of loss of every dollar invested in that way. Therefore, we cannot hesitate to counsel our friends to organize their mining ventures, whenever practicable, only under the laws of a State that authorize and regulate assessments. Having thus provided for the mutual ready support and equal contribution of means for the prosecution of the enterprise by all the shareholders according to their respective interests, let care be taken to select men of unblemished business standing for the management, and we conscientiously believe the larger part of the mining schemes now before the public offer more certainty of profitable outcome upon the money invested in them than in any other industrial undertakings."

THE Massachusetts State Greenhackers at Boston have nominated Gen. B. F. Butler for Governor and Wendell Phillips for Lieutenant Governor.

THE loss of cotton in Louisiana and Mississippi from the late storms is placed at 250,000 bales, and of sugar in the former State at 50,000 bogheads.

A RICH vein of silver is said to have been discovered at Meredith, N. H.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Grantsville, Nevada.

EDITORS PRESS:—From Austin, south, up the wide, even, regular valley of Reese river, some 65 miles, with lofty, rugged ranges of mountains on each side, and the traveler turns over a moderate divide to the west to enter a new, small mining village called Grantsville. It occupies a beautiful nook for a site, surrounded by towering, craggy-crowned hills, with a rocky canyon outlet to the west. It has just room enough for a good town, with water and wood sufficient for all necessary uses. Here are large mines, of late development, very rich in silver and gold, sure of permanence, and worthy to be classed among the first in the State of Nevada.

The principal claim is that of the Alexander, a union of three old ones, yielding only silver and running along near the crest of a precipitous, rocky mountain, most easily to be got at and worked. The ore is the chloride, so soft as rarely to need blasting, with no waste rock, and averaging between \$30 and \$40 to the ton. The vein is an enormous one, surpassing at the point of practical development, anything we have elsewhere seen. It has been opened along the distinct footwall near 600 feet, but only at one point has the effort been made to work fully across it. At this point the superintendent, Mr. San Pedro, and the foreman, Mr. Murphy, conducted us from the footwall 300 feet to what was the day before struck as the supposed hanging wall; but the morning's workman said no, this is only a little shaling in the vein, for at the bottom it is broken through, and the vein yet extends further. We examined, and such was the case; the vein was not yet cut the full width. For this 300 feet there had not appeared one foot of waste rock. This vein is traced by its croppings, and claimed three or four miles, but it is nowhere else opened by regular work.

An excellent 20-stamp dry-crushing and roasting mill is connected with this claim, to which the ore is brought at the small expense of 10c a ton, so conveniently is everything arranged. This mill seems admirably managed under the careful, efficient direction of an experienced foreman, Mr. Thos. Mitchel, formerly of Belmont and Austin.

Everything in connection with the building of this mill and the opening of this mine has been done in two years, without assessment or outside investment, except from the sale of a part of the working capital at first set aside, all expenses being met by returns from the mine itself.

Besides this great Alexander vein there are also other parallel, distinct veins of different character of rock, of which the main one is some 700 feet west. Its principal claim is the Lloyd, opened 60 feet deep, of very hard quartz, and hearing twice the value of gold it does of silver. The vein is 4½ feet thick, and assays immensely rich, much of it from \$300 to \$500 the ton, with no real waste rock.

It is but two years since work was successfully commenced at this point. Yet a New York company had once, some twelve years ago, purchased the claim here and run tunnels to develop the vein. The upper tunnel was 800 feet long, beginning in a slight bend of the footwall, so that they soon lost the vein itself, and then ran parallel with it the whole 800 feet—never over two feet from it, and sometimes but six inches. Then becoming discouraged, all was entirely abandoned till two years ago, when Mr. San Pedro, with a company, began work, and struck the true immense lead, with the results described. But we may not delay too long on one account.

North of Grantsville, in the same range nine miles, is the once prosperous mining town of Lone, with its many once rich-paying veins.

Again, 12 miles across the smooth valley to the west, is another older mining town called Ellsworth, once flourishing, but now very still. Yet, surely, from all we could learn, there are here claims which have not only been worked with rich returns, but in a manner for immediate yields; which, with proper treatment in view of permanence, must become again of immense value. Let men of capital turn their attention to these mines, and they may be largely rewarded.

Again, over the mighty range to the west, across another valley, some eleven miles in all, is a fine mill and claim, with a village called Lodi. The claim is known as the Illinois. This has been a rich, fine, good yielding claim under the successful superintendence of Mr. Kirkpatrick, but some company difficulty has caused a suspension of the smelting furnace since the 25th of last December. It is expected that this claim will again be yielding its full quota of silver in the course of weeks or months; it is not certain how soon.

Eight miles south of here, across the valley which here suddenly bends, thus taking one down to the east side, is the new town of Downville. Here very fine galena silver leads were struck two years since, and have been developing nearly as largely and richly as those of Eureka.

The character of the ore and the peculiar-

ties of the mine are almost exactly the same in both places, and we see no reasons why, with capital, this place might not become second Eureka. The principal vein has been worked in the two years over 600 feet deep, by hand-windlass alone, and there seems no question as to its size and richness.

This hand-work along the irregular lead, as all such leads in line are, has been very expensive, requiring seven successive windlasses from the bottom up. Now a perpendicular shaft, with hoisting works is needed, and the whole enterprise must move off easily and with good returns.

Mr. A. J. Howk, the enterprising merchant of this place and of Ellsworth, is, we understand, now at the Bay to secure the needed funds for this purpose, and we wish to add every encouragement to the effort, believing it must be a good investment.

But from here, 20 miles west to Hot Springs, then near 50 miles south to New Boston, through a grand region of wide valleys and wonderful mountains, especially along under the Volcano range, there are no mines developed, though scores of them are spoken of as claimed and partially prospected.

But at New Boston is a fine crushing and roasting mill, reducing the ore from two or three fine mines, all under the ownership of Mr. A. I. Rhodes & Co. Water is brought in iron pipes four miles across the valley from the east, sufficient for all purposes, and a pleasant, new town is springing up in regular and good shape. From all accounts this is an enterprise of excellent promise, already yielding good returns above all expenses, and promising largely for the future. The more we see and learn of the mineral resources of Nevada, the more we are surprised at their numerous, extended and immense developments, and believe that not one-twentieth part are yet thought of, but for a thousand years to come, they will be more and more constantly unfolding. S. V. B.

Globe City, Globe District, A. T.

EDITORS PRESS:—Having been stopping in this district for several months, I thought I might be able to give the public some information in regard to the mining interests here. I will merely state what I have learned by personal examination, since my arrival, and must say that I am surprised, for from what information I could gather at San Francisco and thereabouts, I expected to find a camp in which the bottom lay very close to the surface, and of course, if I found a shaft of any great depth, to find the bottom not so rich. I took great pains to satisfy myself as to the permanency of the ledge, also the amount and quality of the ore in the bottom, and as yet, I have got to find the first one that did not have a better showing in the bottom than on the surface. Then another thing I have noticed is the length of the ledges, many of them traceable for several miles in length, and the croppings showing great width. I have been forced to believe that deep mining will bring to the surface large quantities of pay ore, as the surface I think has produced as rich ore as any camp discovered. I could, if space would allow, cite to you several claims whose records are second to none yet discovered on this coast, but as most are conversant with the facts, I'll forgo repetition and will try and show other features, which I think ought to be mentioned, that is our large amounts of what is called second class ore, ranging say from 80 to 150 ounces per ton, which at the present time is almost useless to the parties who have taken it out, and own the claims it came from. In many cases this ore was what was left from the sorting, the assorted paying in the thousands, and in several it being the quality coming from the ledge, and in such cases I think it would mill better figures than I have placed it at. Now to the reason of the accumulation of this ore, and we find the miners all say that it runs in debt to take it out, and have it milled at the prices we have to pay and the per cent. we get in return; so they had rather let it lie until they either find a purchaser or it can be worked, and they come out even or ahead. That would of course start them to developing, as most of them have invested their all in these prospects, and have had to quit until something of that kind should be started. I find that a great many of these men would dispose, if they could, some of their best property at a reasonable price, in order to get money to develop their other prospects; and as a general thing, the most of this property has a good showing, with shafts from 50 to 150 feet deep, and good ore from the top to the bottom of shaft, and, in most cases, quite a quantity on the dump; in most of the deep shaft levels have been run and good ore found. So, taking it as a whole, I see no reason why such property (if handled properly) would not be a good investment, providing the parties buying would work the ore with their own reduction works, managed by competent men, and that is what has been the great trouble here. Men have been placed in positions requiring men of experience, that perhaps had never been in a quartz mill before, and the result is the parties interested have got disgusted and quit, and think the country is good for nothing. On this point I could cite you to several cases, and my advice to those parties is, send down competent, well-informed mining men, who understand taking out and reducing ore, and then I think they

will have a better feeling towards this country, and perhaps regain what they have lost and reap a benefit besides. From what I can learn by observation, there has been sent to this country a lot of men, who, it seems, were good for nothing at anything, and so, to get rid of them, shipped them to Arizona to spend their money in trying to learn mining without a teacher; and because it proved a failure in most cases, they say, "no use going there—nothing in it." Having shown you how a few things have been operated, I will say a few words regarding facilities for reduction works. These are, as a matter of course, unusually scarce, still I find that plenty can be had near most of the mines. I hardly think ore would have to be hauled to exceed two miles at the farthest; wood can be hought anywhere in the district at \$5 per cord; labor at your own prices at the present time. So, taking it altogether, I see no reason why ore should not be worked here at a very reasonable price; and as a large per cent. of our ore is free milling and quite a considerable carries free gold, I am at a loss to know why this camp should not command the attention of some of the mining men of the Pacific coast; and I think when it does have a fair and impartial trial, that there will be brought to light things that will be enticing to all who have capital to invest. MINER.

Sept. 6th, 1879.

The High Sierras.

EDITORS PRESS:—We had been having a prolonged spell of extremely hot weather, and wife, baby and I, to get away from it, started for our eastward horizon of snow, the high Sierras. The ascent of the mountain is made by an excellent wagon road, constructed for hauling lumber from the four large mills, which, from the immense mountain forests, have supplied our valley with lumber.

Our first half day of mountain travel took us to an altitude of some 6,000 feet; here at Stevenson's dairy ranch, a beautiful meadow of green native grass, surrounded by a dense, untouched forest, mostly of the larch timber (*Larix Americana*), we spent our first night in the mountains. The next day, five hours' travel, 15 miles in an easterly direction, over altitudes varying from 5,000 to 7,000 feet, took us, to the end of all the wagon road here on the mountains, to Dusy's sheep ranch on Dinkey creek. Mr. Dusy is one of the pioneers of this country. He is one of our county's most successful sheep men. His thousands of sheep find abundant, excellent summer pasturage under his personal supervision and direction, in the numerous small mountain meadows along the headwaters of King's river. He is an artist and has taken numerous views of the most noted and picturesque scenery in the mountains. His family spends a portion of their summer at Dinkey creek. Here I left wife and baby and started out for a day's hutzling. I went eastward a dozen miles across Dinkey and up the North Fork of King's river; then I went northward to an altitude of between 800 and 900 feet.

Dusy's Grove of Big Trees.

Many persons speak and write of the "Big Trees," as though there were but a single grove. The truth is, there are about a dozen groves of them. I had before seen over a half dozen groves in Tulare county; the Mariposa grove, the Calaveras grove, and now we were to visit Dusy's grove, one of the two noted groves that I'd not yet seen, the other being further north on the head of Fresno river.

This grove of sequoias is about four miles down Dinkey creek from Mr. Dusy's place, is on the opposite side from Mr. D.'s, and about a half a mile from Dinkey creek, and I should think nearly a thousand feet higher than the creek, which here runs in a canyon.

There are over 100 trees (my estimate) in the grove. The smallest, a foot in girth, we brought away. The largest, named Gen. Washington, by Mr. Dusy, the discoverer, is nearly half burned away at the butt, but it shows an original diameter of 44 feet at the surface of the ground. Some of the trees of a diameter from 20 to 25 feet, are the most symmetrical of all sequoias that I have ever seen. They show a scarcely varying uniformity in size of trunk for a height of over 100 feet.

Vandalism.

This sub-head may sound harsh, but no milder one will express the way that some of these trees have been mutilated. There is an abundance of bark and wood obtainable from fallen trees; this ought to suffice; but it does not. Visitors have mutilated some of the finest trees in the grove for relics to carry away. I believe that, had the body of Washington, the revered "Father of our Country," been embalmed, so that we could look upon his features as in life, there are people who would not be content without breaking off a piece of an ear or digging out an eye to carry off as mementoes of their visit to his tomb.

This ought to be stopped. One of these forest giants must soon yield its life to the rapacity of these relic hunters. But that is not the end. Other trees will follow in disfigurement and destruction, as the number of visitors increases, until all will be deformed and dead; victims to a practice which, by statute, ought to be made criminal.

Hospitality.

During the last dozen years a great number of

tourists have visited this grove. Mr. Dusy has furnished free use of inclosed pastures to the many hundreds of horses that have been ridden, and driven by these excursionists. I asked him if he intended for future years to bestow a like favor gratis to all visitors to the grove. "Yes," said he, "tell everybody to come, while I'm proprietor here; in the future as in the past, no visitors to the grove will be charged for pasturage of work animals."

He then related circumstances pertaining to visits of different tourists. Notably among them John Muir, who made this his starting point on that long trip of extensive explorations in this "Switzerland of America."

Fresno, Cal.

W. A. SANDERS.

Coal Mines in China.

The *Shen Pao* publishes a report on some coal mines in the neighborhood of Ching-men-Chow, not far from Iohang. The report is written by a mandarin who was sent to make an inspection, and was evidently accompanied by a foreign expert. Boring operations, says the report, were commenced late last autumn. The coal-producing country appears to cover an extent of 75 square English miles, 15 long by five broad. There are ten layers of coal one above the other. The bed in Wotzkow is estimated to be 500 English acres; that at San-li-kang to be one-fourth its size. It is supposed that 1,200,000 tons of coal can be raised from Wotzkow, and 800,000 from San-li-kang, at the rate of 40,000 tons a year. The supply thus would last at least 40 years. It is highly probable that further explorations will bring to light fresh beds, as these discoveries are the result of merely the first investigations. It should be mentioned that a few small mines have been opened by the people living in the district, but they have not penetrated to the level of the best coal or largest seams. The bed at Wotzkow is 100 feet below the surface. The coal is just the same as the best American anthracite that is brought to China. Anthracite is a most useful kind of coal, being free from sulphur and without any impurities. It gives out great heat and can be used economically and successfully for smelting iron or other metals. It is also suitable for use on hoard steamers, particularly when mixed with soft coal. As affording much heat, with but little smoke, it commands a high price for household purposes. A small proportion only of the coal throughout the world is good enough for smelting, and any foreign country possessing coal of as good quality as that at Wotzkow, would be content to carry it hundreds of miles to its smelting furnaces. Specimens of this and of all the native and foreign coal procurable in China have been analyzed together, and the new coal has shown itself superior to all for smelting purposes. The province of Hupei possesses several mines containing iron of excellent quality. If these are worked in connection with the coal mines, large profits should be obtained, and if the example be followed in other provinces, a source of wealth to the whole country will be opened up.

BELT LACING.—A mill-owner says: "Belts make the best possible strings for lacing belts. One lace will outlast any belt, and will stand wear and hard usage where books or any other fastenings fail. Our mill being on the bank of the river, we keep a net set for eels, which, when wanted, are taken out in the morning and skinned, and the skins are stuck on a smooth board. When dry, we cut them in two strings, making the eel-skin, in three hours from the time the fish is taken from the water, travel in a belt."

DRILLING GLASS.—Take a common drill, run a little fast; do not press on, the weight of the drill-press is enough. Drill from both sides, keeping the glass and drill wet with turpentine. Be very careful when the two holes meet, not to let the drill catch. After a hole is made large enough for a small round file, file to the desired size, keeping the file and glass wet with turpentine.

LABOR-SAVING JIGS.—Where great quantities of slate are found in veins of anthracite coal, and the slate is hard and heavy, a jig or separator is now used to separate the slate from the coal. This used to be done by children. A superior jig has been adopted from an old German machine, in which a powerful plunger is used to agitate the water instead of the lifting process which is applied to all others.

BENZOLE AND BENZINE.—Benzole and benzine have been generally regarded as synonymous, but certain pharmaceutical works now apply the term benzine to a light petroleum product. True benzole is soluble in half to three quarters of its weight of alcohol, while the petroleum spirit requires six times its weight.—*Exchange*.

CLEANING BOTTLES THAT HAVE CONTAINED ESSENTIAL OIL.—The bandiest way is to put a little powdered bichromate of potash in the bottle, then as much in bulk of concentrated sulphuric acid. Let it run well round, and then let it stand till the organic particles are carbonized or turned black. Add a little water, shake well, and rinse out.

A PNEUMATIC DISPATCH TUBE.—Shavings from a planing mill in Chicago are, by an air-lift, blown 700 feet, through a 15-inch sheet iron pipe, to a distillery, where they are burned for fuel.

MECHANICAL PROGRESS.

Pitch of Tuning Forks.

An optical method has been devised in England for determining the absolute pitch of tuning-forks. The fork vibrates in front of a rotating drum, whose periphery is marked with dots or fine lines at regular intervals. A microscope is so arranged as to comprise in its field of vision the edge of the fork, and several of the intervals upon the drum. When the drum revolves at such a rate that the speed of an interval equals the period of the fork, a set of waves or prominences, in width equal to an interval, becomes visible. A Koenig fork, giving 256 vibrations per second, correct at 16.1° C., was tested, and gave 256.2966. Frequent bowing did not alter the phase; but fixing the fork rigidly, as in a vise, did so. The temperature coefficient for Koenig's forks (0.00011 for each degree Centigrade) was confirmed by these tests. Forks of different octaves were compared; audible beats could be counted; and modifications of Lesage's figures seen. The time in this experiment was got by an electric clock, designed by Prof. McLeod, which is described as follows: A zinc and steel compensating pendulum, moved by its own gravity; but at each beat made and broke a battery-circuit, by means of two bent springs, one on each side. The current passing through an electro-magnet, detained a bent lever until the pendulum swung to the other contact. By this contrivance time was marked. The platinum contacts frequently struck together; but a liquid shunt of dilute sulphuric acid destroyed the extra current and remedied that defect.

SELF-LAYING TRAMWAY.—A vehicle was on exhibition at the recent Royal Agricultural show, which excited considerable attention from the fact that it was a road-car carrying its own rails or trams and laying them as it moved. The tramway is composed of plates of hard wood, faced and strengthened with metal, and attached to two parallel endless chains, which pass round revolving guides or drums at the ends of the vehicle, and both over and under the wheels. The chief points in which this arrangement differs from others of a similar character are the gain of a fixed rail without loss of power by friction, the endless chain of plates resting on the top of the van wheels, and being carried forward by them. In this way a free and noiseless action is secured. The under carriages, constructed on the bogie principle, lock simultaneously, thus causing the front and hind wheels to run in the same track, and also enabling the vehicle to turn a very sharp corner. The shafts, however, can be fixed at either end, so as to avoid the necessity for turning in narrow or inconvenient places. The body of the vehicle projects over the wheels, thus giving an increased capacity of over 30%. A light four-wheeled van, fitted with this apparatus, and loaded up to one ton weight, may easily be drawn by one man; and over very heavy or plowed land, the gain is proportionally greater. In this latter case the plates of the endless chains are constructed of a sufficient width to well cover furrows or ruts. The first two vehicles that were constructed under this patent were a farm wagon capable of carrying from seven to eight tons, and a vehicle for goods or passengers, suitable for high speed.

THE MELODIOPHON.—Several contrivances have been invented to record the notes of melodies played on a piano, organ, or other key instrument, but were all more or less useless on account of their complexity, imperfectness, or expense. Zigliani's melodiophon is very simple, usable and cheap. A double flat spring placed under each key is connected with a battery and with a recording apparatus, which consists of a comb provided with insulated teeth gently resting on a copper cylinder. A strip of ruled and chemically prepared paper is drawn over this roller by a clock-work, and receives the impressions or marks of the teeth of the comb. This clockwork can be regulated so as to cause the paper to move in conformity with the time kept by a person playing the instrument. Every time a key is depressed the circuit is closed, and the electricity, passing through one of the teeth of the comb, makes a mark corresponding to the key that has been depressed.

A CHEMICAL CLOCK.—There is a clock in the Guildhall Museum, London, of which the motive power is hydrogen gas, generated by the action of diluted sulphuric acid on a ball of zinc. The clock itself resembles a large colored glass cylinder without a cover, and is about half full of sulphuric acid. Floating on the top of this acid is a glass bell, and the gas generated forces upward this concave receiver until it nearly reaches the top of the cylinder, when, by the action of a delicate lever, two valves become simultaneously opened. One of these allows the gas to escape, thereby causing the receiver to descend, and the other permits a fresh ball of zinc to fall into the acid. The same operation is repeated as long as the materials for making the gas are supplied, and this is effected without winding or manipulation of any kind. The dial plate is fixed to the front of the cylinder, and communicated by wheels, etc., with a small glass perpendicular shaft, which rises with the receiver and sets the wheels in motion.

A HOME-MADE DANIELL BATTERY.—The London *Electrician* gives the following directions for making a Daniell cell: Select a small round earthenware jar, such as is used for keeping preserves, and, having lined the bottom with gutta-percha, or some suitable cement, to the depth of one-quarter inch, fix upright in this a rod of zinc, of equal height with the jar, to which a length of copper wire has been attached by passing it through a hole drilled in the upper part of the zinc rod, or by soldering. Make a cylinder of pipe-clay, or other porous clay, larger than the zinc rod, and having dried it, make it hot in the fire by degrees, till it attains a red heat. Let this cylinder cool gently, and when cold place it in the jar round the center rod, encircling it at a little distance. By moderately heating the end of the cylinder, it will, when placed on the gutta-percha, make a groove which will fix the tube and prevent infiltration of the fluids. Line the inside of the jar with a plate of thin copper bent into a cylindrical form and having a few holes punched in it, through which may be threaded the extremity of another length of copper wire. On the top of this cylinder place a flat ring of copper pierced with holes, and nearly, but not quite, touching the porous cylinder. This forms the battery. To charge it, a saturated solution of sulphate of copper is poured between the copper and the clay tube, and some crystals of the same salt are placed upon the perforated ring so as just to be in contact with the solution. The zinc compartment is then to be filled with a solution of sulphate of zinc, sal-ammoniac, or common salt.

POLYMER FOR GRADING RAILWAYS.—The apparatus generally used for testing the distance between the rails and the super-elevation is merely an iron bar with two lugs or gauges—on which a mason's level is placed—and a notched rule, which, of course, must be horizontal. To secure greater accuracy in both these operations, M. Couturier has invented his polymer, which consists of an iron triangular rule about 6½ feet in length, having the long side of its base, furnished with a movable arm which is pressed against the rail by a spring. The arm communicates with a pointer, which stands at the zero of a finely divided scale when the rails are at their nominal width apart, 1.447 meters (4 feet 8½ inches); for instance, any deviation from this, more or less, being indicated on the scale. At the side a pendulum is attached to the ruler, which, when vertical, points to the zero of a circular scale; any change in the inclination of the ruler is communicated to an index sufficiently long to reproduce on the scale the actual amount of the super-elevation of the rail; this communication can be made either by a toothed wheel or by a series of links from the pendulum to the index. This second part can, if necessary, be detached from the ruler and placed in a box, which could then be laid upon the ordinary gauging bar. It is fitted with a glass covering to protect it from dust and from injury at the hands of the plate layers.—*Abstract of a paper in Bi-mensuel de la Société d'Encouragement, 1878.*

CURING BEEF BY INJECTING BRINE.—The infiltration system of salting beef, by filling the blood-vessels with brine, is attracting considerable attention in Australia. In some recent experiments at Brisbane, bullocks were treated as follows: At the instant of killing, the animal's heart was laid bare, and incisions were made in both ventricles. Into the orifice of the left ventricle a pipe was inserted, and a stream of weak brine was forced through the blood-vessels, washing out all the blood. Pressure was obtained by having the brine in an elevated tank. After the expulsion of the blood, the right ventricle was closed by a clamp, and stronger brine was forced in until all the blood-vessels were full. In this way the distribution of the brine through every part of the meat is said to be complete and the curing perfect. It is proposed to send to the Sydney exhibition a whole bullock thus preserved.—*Scientific American.*

NEW RAILROAD TIE.—A new iron railroad tie recently exhibited at Philadelphia dispenses with the use of spikes, bolts, nuts, or fish plates, and with the drilling and punching of rails, and avoids the consequent dangers of weakening or fracture from such causes. The mode of attachment is by means of a recess, with which each tie is provided, along the bottom of which recess wedge-shaped transverse pieces are cast. At the side of the recesses are two crooked blocks of wood, which form a cushion and a fulcrum for two clamps, which grasp the flange and web of the rail above, bearing upon opposite faces of the wedge below. By this device the weight of the train increases the grip of the clamps. The first cost of this tie is greater than that of the wooden tie, but it is claimed that this is more than offset by its much greater durability.

INDIA-RUBBER TIRES.—A gentleman read a paper before the recent meeting of the Institution of Mechanical Engineers at Glasgow, in which he claimed that the rubber tires used on the traction engines of India were of great service in reducing the cost of the ordinary engine repairs, and in giving uniformity of adhesion, without damaging the surface of the roads. The cost of the tires did not exceed 1½d. per mile. The manager of the Glasgow tramway stated that the engines used by him were provided with rubber tires, without which they would be unable to secure sufficient adhesion to enable them to do their work.

SCIENTIFIC PROGRESS.

Edison's Discovery.

Mr. Edison has not yet revealed any additions to his knowledge of the use of electricity for illumination, but his paper on the treatment of platinum wire, read at the session of the American Association for the Advancement of Science at Saratoga, is almost as interesting as a discussion of the electric light would have been. Platinum, made incandescent by a hydrogen flame or by an electric current, wastes away or burns until nothing is left. This prevents its use for illuminating purposes. He found this to be caused, not by volatilization, a generally understood, but by detritation, the currents of gas rubbing off fine particles. He prevented this by coating the wire with oxide of magnesium.

By further experiments Mr. Edison supplemented Dr. John W. Draper's discovery that platinum wire in a Bunsen flame becomes disintegrated. He states in his paper the fact that all metals have air spaces in them, and that these interstices are the origin of the cracks which become visible through a microscope after incandescence, and to the naked eye in platinum if a wire is stretched between clamp posts. These being the conditions, Mr. Edison put his platinum under the receiver of a powerful air-pump, and by alternately subjecting it to the action of a vacuum and sending an electric current through it to aid the expulsion of air by warmth, he produced a wire in which "no cracks were visible" by the microscope. "The wire had become as white as silver, and had a polish which could not be given it by any other means. The wire had a less diameter than before treatment, and it was exceedingly difficult to melt in the oxyhydrogen flame. As compared with untreated platinum, it was found that it was as hard as the steel wire used in pianos, and that it could not be annealed at any temperature."

Mr. Edison adds: "My experiments with many metals treated by this process have proved to my satisfaction, and I have no hesitation in stating that what is known as annealing metals to make them soft and pliable is nothing more than the cracking of the metal. In every case where a hard drawn wire has been annealed a powerful microscope revealed myriads of cracks in the metal."

Further experiments showed that a very much higher illuminating power could be obtained at a much less expenditure of force than in the original platinum. He has made, in fact, a new kind of platinum, and other metals, by the same process, are transformed in the same manner.

Friction of Fluids Against Solids.

A plank drawn through water suffers (as is well known) a resistance varying as to the square of the velocity; while a current of water is retarded measurably by the drag on the banks and on the bottom. The center of a stream, moreover, travels faster than the sides, and the different fluid layers rub against each other.

Prof. Unwin, of London, has devised a special apparatus for determining the frictional resistance in such cases. His device consists of a metallic disk, rotated on a vertical axis in a vessel of water. Within the outer vessel is a thin copper chamber; and within this chamber, the disk is placed concentrically; so that there are two cheese-shaped masses of water—one above and one below the disk—which are dragged into rotation next the disk and retarded next the sides of the pan. This chamber is suspended from three wires, in such a manner as not to obstruct its tendency to rotate when the motion is uniform. An index marks on a graduated scale whether it rotates or not, while a weight hung by a cord measures the force required to keep the index at zero. The results obtained are not ready for publication; but the author mentions that a rough cast-iron disk has a frictional resistance almost exactly as the square of the velocity, while in the case of a turned brass disk, the resistance increased in a decidedly smaller ratio. The resistance increases slightly with the mass of water.

RUNNING A LOCOMOTIVE WITH AIR.—An amusing incident in the career of Mr. A. L. Holley is related by a New York paper. While working as an engineer on one of the railways he made a wager with some of his fellows that he could run a locomotive a mile without fire, water, or steam, the locomotive to be taken empty and cold from the shop, and towed by another engine to a point at some distance on the road, where a level stretch of track favored the experiment. Young Holley rode in solitary state on his cold locomotive to the scene of trial, and, unsuspected by his escort, so arranged matters that during the trip the motion of the drivers and pistons stored the boilers with compressed air! This gave him, by the time the destined point was reached, an accumulation of power by means of which he ran his mile and won his wager.

New Planets.

Perhaps no scientific achievement during the present century has been deemed more marvellous than the discovery of the outermost member (so far as is known) of the sun's family of planets. In many respects, apart from the great difficulty of the mathematical problem involved, the discovery appealed strongly to imagination. A planet, 1,700,000,000 miles from the sun, had been discovered in March, 1771, through a more accident, though the accident was not likely to occur to anyone but an astronomer constantly studying the star-depths. Engaged in such observations, but with no idea of enlarging the known domain of the sun, Sir W. Herschel perceived the distant planet, Uranus. His experienced eye at once recognized the fact that the stranger was not a fixed star. He judged it to be a comet. It was not until several weeks had elapsed that the newly discovered body was proved to be a planet, traveling nearly twice as far away from the sun as Saturn, the remotest planet before known. A century only had elapsed since the theory of gravitation had been established. Yet it was at once perceived how greatly this theory had increased the power of the astronomer to deal with planetary motions. Before a year had passed more was known about the motion of Uranus than had been learned about the motion of any of the planets during 2,000 years preceding the time of Copernicus. It was possible to calculate in advance the position of the newly discovered planet, to calculate retrogressively the path along which it had been traveling, unseen and unsuspected, during the century preceding its discovery. And now observations which many might have judged to be of little value came in most usefully. Astronomers, since the discovery of the telescope, had formed catalogues of the places of many hundred stars invisible to the naked eye. Search among the observations by which such catalogues had been formed revealed the fact that Uranus had been seen and catalogued as a fixed star 21 several times! Flamsteed had seen it five times, each time recording as a star of the sixth magnitude, so that five of Flamsteed's stars had to be cancelled from his lists. Lemonnier had actually seen Uranus 12 times, and only escaped the honor of discovering the planet (as such) through the most marvelous carelessness, his astronomical papers being, as Arago said, "a very picture of chaos." Bradley saw Uranus three times; Mayer saw the planet once only. It was from the study of the movements of Uranus as thus seen, combined with the planet's progress after its discovery, that mathematicians first began to suspect the existence of some unknown disturbing body. The observations preceding the discovery of the planet range over an interval of 90 years and a few months, the earliest observation used being one made by Flamsteed, on December 23d, 1690. There is something very strange in the thought that science was able thus to deal with the motions of a planet for nearly a century before the planet was known. Astronomy calculated in the first place where the planet had been during that time; and then, from records made by departed observers, who had had no suspicions of the real nature of the body they were observing, astronomy corrected her calculations, and deduced more rigorously the true nature of the new planet's motions.—*R. A. Proctor, in the Contemporary Review.*

FIRE WITHOUT COAL.—We publish the following extract from a letter of Miss M. Betham Edwards to the London *Athenaeum* for what it is worth. Miss Edwards is well-known in England as a writer, and some credit may be placed in her statement: "I send you the following particulars of a recent scientific invention, just patented, and destined without doubt to play a very important part in our economic history. I think it must be regarded as a solution for once and for all of the great coal question, or rather fuel question, not only among ourselves, but abroad. M. Bourhonnell, of Dijon, the celebrated lion and panther slayer, lighted upon the following discovery by hazard, and after six years' persistent investigation brought it to entire 'workable' perfection. He discovered by means of two natural substances, inexhaustible in nature, the means of lighting and maintaining a fire without wood or coal; a fire instantaneously lighted and extinguished; a fire causing no dust, smoke, or trouble; a fire costing one-tenth at least of ordinary fuel; and, what is more wonderful still, a fire the portion which answering to our fuel is everlasting, that is to say, would last a lifetime. M. Bourhonnell's invention comprehends both stove and fuel. The fires could be on the minutest scale or on the largest. They would be used for heating a hasty food or for roasting an ox. Being lighted instantaneously they will be a great economy of time. M. Bourhonnell at once patented his invention, and a body of engineers and savants from Paris visited him, and pronounced his discovery one of the most remarkable of the age. He has had several offers for the purchase of the patent in France, but wants to sell it in England, his own occupation being in another line. Any English gentleman or firm wishing to see his fires and stoves could do so by writing to him a day or two hereafter. His address is M. Bourhonnell, Dijon. . . . I have seen these fires and stoves. There is no mistake about the matter. It is as clear as possible that here we have a perpetual and economical source of fuel. Two hundred years ago the discoverer would have surely been burnt as a wizard."

The Auriferous Gravels of California.

(A paper read before the California Academy of Sciences, Monday evening, September 16th, 1879, by W. A. GOODFRIEND, M. E.)

In the year 1871, the writer, as an assistant on the State Geological Survey of California, under Prof. J. D. Whitney, spent about six months of active field-work in a careful investigation of that portion of the auriferous gravel region of California which lies between the north fork of the American river on the one hand and the Mokelumne river on the other, including the greater portion of Placer county and the whole of El Dorado and Amador counties, so far as these ancient gravels extend from the very base of the mountains, along the edge of the Sacramento valley, northeastward towards the crest of the Sierra Nevada range.

This investigation was constantly accompanied and checked on all important questions involved in the complex problems to be solved by instrumental measurements and observations, as accurate as could be made with such instruments as are portable for a man traveling in the saddle, and especially by a continuous series of exceedingly numerous observations for altitude with the best mercurial barometers.

It is safe to say, that no other equally extensive portion of the gravel region of California has ever yet been so carefully and systematically studied by any single person. I am also tolerably familiar with the gravel formation so far as it extends in Calaveras county, and have at various times visited many other localities in Nevada and Sierra counties and elsewhere.

I believe that my field-work in 1871 sufficed beyond all reasonable doubt to solve, in general terms, the whole problem of the dynamic origin of the ancient auriferous gravels of California.

During the last eight years, however, I have written nothing for publication upon this subject, not because of the absence of temptation to do so, but because I have been restrained therefrom, first, by the consideration that this work having been done in the service of the State of California, its results were the property of the State, and ought to make their appearance only in such manner, and through such channels of publication as the State might deem fit to provide; and second, since the State for seven years now has declined to make provision, either for any further investigation of her resources in this direction, or for the publication of the results which had already been obtained, I have felt that if any single individual possessed under such circumstances a stronger claim than another upon the results of my own work, that individual was Prof. Whitney, who was State Geologist at the time, and under whose direction and supervision the work itself was done.

But circumstances change, and after the lapse of eight years, the regents of the University of California having some time since given permission to Prof. Whitney to use so far as he could for purposes of publication, the material which he had previously accumulated, the Museum of Comparative Zoology, at Cambridge, Massachusetts, has furnished the financial requisites for the publication of part of this material. And consequently a large pamphlet (288 pages of somewhat larger size, but otherwise very similar in general style of publication to the previously published reports of the State Geological Survey of California) was published early in April, 1879.

This pamphlet constitutes the first part of No. I., Vol VI., of the Memoirs of the Museum. Only 300 copies of it were printed, and these are exclusively at the disposition of the Museum, and will be distributed to those on its regular exchange list.

It is the first portion of a volume on "The Auriferous Gravels of the Sierra Nevada of California," by Prof. J. D. Whitney.

The pamphlet already published contains a large part of the results of my work in 1871. But this part consists chiefly of a detailed statement of observed facts, without, however, including any results of the barometric computations of altitude, and the whole matter of a general discussion of the dynamic history, and the *modus operandi* of the accumulation of these gravels is deferred for the latter part of the volume.

The remainder of the volume was promised in a few months. But in the meantime, after more than 25 years of mining operations among these gravels, all sorts of theories are yet rife as to their origin, and nobody seems yet to know exactly what to think of them.

I therefore propose now to present a few of my own ideas upon the subject gathered from my experience in the field, premising, however, that nobody is responsible except myself for any theory that I may offer. I would say, furthermore, that if in anything which follows I should appear to speak too much after the style of one who teaches with authority, it is not because I wish to do that, however confident I may be of the truth of my observations, but because I am studying brevity, and wish to present my ideas in the shortest possible shape.

The problem of the auriferous gravels of California

is certainly one of the most complex and intricate in its details of all the questions that have ever puzzled geologists in this or any other country. Yet its solution, in broad terms, is comparatively simple.

Nothing like the old "Blue Lead" theory will ever account for it. The idea either of one or several great rivers running for long distances in a direction nearly parallel with the present axis of the Sierra Nevada, is a myth that can never be substantiated. The supposition that the Columbia river ever came through there is simply absurd; and the propositions that these gravels are the work of glaciers, or that they are deposits made in the bed of a lake or sea are equally untenable.

The whole character of these gravels when studied in detail, proves beyond a question, that they are the work of running streams of fresh water. The question is, whence came these streams, in what direction did they run, and how did they act, and what has been the history from that time to this?

I proceed to give that history,—not in the complexity of its details, many of which will never be unraveled,—but as I have said before, in broad and general terms.

As I do not propose to discuss particularly in this paper the lithological or other characteristics of the rocks which, constituting the main mass of the Sierra Nevada, underlie the gravels, and whose degradation furnished the materials of the gravels themselves, I shall here include them all in the one general and convenient name of "bedrock," without distinction as to whether they consist (as they do in different localities) of metamorphic slates and sandstones, or of limestone, or of granite and its kindred rocks.

The first proposition, which it now becomes necessary to clearly set forth, is a most important one, inasmuch as it underlies the whole explanation of the gravel system. It consists in the simple fact that, contrary to what has been a very widely received opinion, the western slope of the Sierra Nevada has not been subjected to any considerable movements of elevation or depression since the commencement of the gravel epoch. I speak now of the bedrock. There are, of course, many localities, especially in the northern portion of the Sierra, where great additions have been made to the height of the range by the enormous mass of volcanic materials which has been piled on top of it. But tremendous as the volcanic energy was for a period, its seat of action lay almost exclusively to the eastward of the gravel region, which was merely overwhelmed with its debris and occasionally shaken by its earthquake throes, without, however, sustaining any considerable change in position or altitude of the bedrock.

This being the case, it is seen at once that the general direction of the drainage of this region throughout the period of accumulation of the auriferous gravels must have been southwesterly, the same as now. And the character and distribution of the gravels themselves, together with the directions of the ancient channels, wherever these can still be definitely traced in the bedrock, proves beyond a doubt that such was indeed the fact.

But, in other respects, this drainage took place under circumstances which were very different from those which exist to-day.

At that time no canyons of any considerable depth existed here, and the western slope of the Sierra was a broad and moderately hilly region 50 or 60 miles in width, having a general average inclination of something like a hundred feet to the mile in a southwesterly direction from near the crest of the range to the edge of the great valley of California, which was then in all probability partially occupied by an extensive but very shallow lake or inland sea.

The hills were not very high, rarely rising more than 200 or 300 feet (often far less) above the beds of the adjacent streams. But there were occasional ridges and ranges of hills which rose much higher, sometimes even 1,000 or 1,500 feet above the immediately surrounding country.

Such, for example, is a conspicuous range or series of bedrock hills, which still stretches in a southwesterly direction from near the crest of the range along the divide between the south and middle forks of the American river, nearly to Georgetown in El Dorado county.

Another prominent example of the same kind is the "Bear Mountain" ridge in Calaveras county, which consists entirely of bedrock, and is situated very low down on the western slope of the Sierra, extending nearly parallel with the axis of the range, and in an almost unbroken ridge easterly from near the Calaveras river to the Stanislaus.

The situation of this ridge is such that it has formed a kind of dam or barrier, to which I shall refer again hereafter.

The outlines of the whole drainage basins of the larger streams during the gravel epoch were of course marked by the lines of these exceptionally high ranges of hills, and wherever these ranges were high enough to tower above the general flood of volcanic debris, which subsequently buried the gravels, there the same ranges still continue to mark the outlines of the larger drainage basins of to-day, and to that extent the present drainage system is identical with the old.

But, as already stated, throughout most of the country the hills were low, and among these lower hills meandered the streams in whose channels the ancient gravels were accumulated. These streams were, of course, extremely crooked, as was necessarily the case in a country

so situated, where there was almost absolutely no plane surface, but all was more or less undulating. Their general direction was easterly. But they often ran for short distances towards every imaginable point of the compass, even something directly northeast towards the crest of the Sierra. Similar cases can be found among the streams of to-day, but they are not so common as they were then. Of course, there were occasionally places where for several miles even the larger streams themselves would run south or southeast—i. e., nearly parallel with the axis of the mountain range, before turning again southwest in their course towards the valley. This was particularly the case in the region northwest of the Middle Yuba river. And this circumstance has been the only basis for the old "Blue Lead" theory, the central idea of which was that one or two or three great rivers had once flowed for hundreds of miles along the western slope of the Sierra in a direction nearly parallel with its crest.

One notable case of this kind (involving no great distance, to be sure, but enough to illustrate the matter) is that of the ancient and modern north forks of the American river. The ancient fork at one time ran from the vicinity of Gold Run, or a little below, and somewhere about Indiana Hill or Illinois Hill, for a number of miles in a direction south or a little east of south through Iowa Hill, and near Wisconsin Hill, to a point somewhere in the neighborhood of Forest Hill or Yankee Jim's, in Placer Co., where it met the old middle fork, and there turned again southwest. The modern fork flows from a point one or two miles northeast of Colfax, in a general direction a little east of south for five or six miles, to the mouth of Shirt-tail canyon. This is indeed a remarkable, and in this region an uncommonly close case of parallelism between the ancient and modern streams. But the only point which I wished to elucidate here was, that the fact of the ancient streams having sometimes flowed for several miles in a south or southeasterly direction has been the occasion and the basis for a "Blue Lead" theory which for many years has misled the people and befogged the whole matter.

The streams in whose channels the ancient gravels were accumulated were generally shallow. Here and there channels were excavated into the solid bedrock to depths of from 100 to 200 feet or more. But these were rather the exceptions, and not the rule.

The streams themselves were in all probability subject to greater variations in the quantity of water which they carried at different times than are the streams of to-day. For example, a stream which at one time only contained water enough to enable it to transport small quantities of sand—or possibly nothing at all unless it were the finest clayey silt—would at other times be subject to heavy and sudden floods which would hurl along great quantities of coarser materials, including sometimes boulders of many tons in weight, a large portion of which materials would, in case of an equally sudden subsidence of the flood, be left behind, and might either be scattered for a considerable distance along the bed of the stream, or, if the stream had overflowed its banks, might be spread broadcast over a portion of the adjacent country.

There can be no question about the power of water—even on slopes of less than one-half of a hundred feet to the mile—to transport boulders as large as any that are found in the gravel region, provided only that the volume of the water be sufficiently great and its rush correspondingly rapid. Nor would it require much time for such a flood to transport heavy materials to considerable distances. It is more than probable that such occurrences were not uncommon during the gravel epoch.

I will call attention here to another point. In those numerous cases where great and broad channels have been found excavated in the solid bedrock by the ancient streams to depths of from 100 to 200 feet or even more below the rim rocks on either side, it is not fair to assume that the same stream had at any one time the same depth of channel throughout its course. On the contrary, it is far more probable that even while these streams were flowing in the deepest parts of their rocky channels, the same streams were in other parts of their courses running between low banks, which in many cases were not high enough to prevent frequent overflows.

But floods heavy enough to transport large boulders occurred only at intervals, and were of short duration; and on the whole, the process of accumulation of these gravels was a slow one, and humanly speaking a very long one. It is not at all unlikely to have occupied hundreds of thousands of years.

I see no necessity, however, for supposing that any long period of excavation preceded a distinct and subsequent period of accumulation. It is certain of course that at any point where the bedrock has been excavated, the excavation at that particular point must have been finished before the same point was finally buried beneath the growing accumulations. But I see no reason why in different localities the two operations should not have proceeded *pari passu*, excavation occurring at one place, while at the same time accumulation was progressing at another. Indeed when we consider the varying grades which the ancient streams must have had, as well as the ever-varying conditions which attended their existence, it seems more than probable that such was the case from the beginning.

These streams flowed at first on the almost naked surface of the bedrock, and necessarily

sought the lowest channels they could find among the inequalities of that surface. The portions of these channels which first became filled with debris, were those where the grade of the streams was gentlest and where, as an ordinary rule, the current was most sluggish. When, however, these portions of a channel had become filled to a certain height, i. e., up to or perhaps a little above the general level of the lower portions of the surrounding country, then the banks no longer proving high enough at all points to restrain the current, the stream at some point or other would burst through or over them, and thus leaving its old bed dry, would seek out a new channel for itself among the adjacent knolls and hills for a distance which might vary according to circumstances, from a few rods to several miles. The new channel would be crooked like the old one, and in due course of time would become filled in its turn with debris, when the stream would again burst its banks and choose still a different course. And thus the process went on slowly but surely, not with one stream merely nor with several, but with the hundreds, nay, the thousands of streams that constituted the whole drainage system of the mountains, until at length, over extensive regions, all the lower depressions were filled with gravel, the lower knolls themselves were covered with it, and as its depth increased, it crept steadily higher and higher up against the sides of the larger hills, and every square foot of the buried surface of the bedrock was worn and smoothed by the streams which brought its gravel covering.

It will readily be seen that in the later stages of such a history, and after the accumulation of gravel had already become considerable, it would have been no uncommon thing for one of these shifting streams, in changing its course, to choose a new one directly or obliquely across the top of an already filled and more ancient channel. In such a case, the new stream might either begin at once to deposit a new accumulation of gravel on top of the old one, or, what is quite as probable, it might first excavate through the older deposit a new channel of greater or less depth for itself, which channel would then be subsequently filled by later accumulations in its own bed, the question whether a given stream, at a given locality, and a given time, would act as an excavator or a depositor of material being determined partly by existing accidents of local topography, but probably very largely also by certain transitory conditions of the stream itself, such as the volume of water which it carried for the time, and other circumstances, which have left no discoverable intelligible record behind them, and which no man can ever hope to fully trace out.

Such occurrences were in fact extremely frequent during the gravel period, and it is this fact more than all others which has produced such infinite complexity and apparent confusion in the present structure of the gravels, and rendered the whole problem so exceedingly intricate in its details and so difficult to solve.

Thus, in the course of ages, the auriferous gravels were accumulated and irregularly distributed over the broad expanse of the western slope, from the very foot of the mountain range up almost to its towering crests.

In many places, of course, the gravel was not very deep, and there were extensive areas which probably never had more than a foot or two of gravel distributed over them. But in other localities, where the topography was favorable, and the larger streams had an opportunity to work uninterruptedly and with but little change in their position for immense periods of time, the accumulations were enormous, and many square miles of country were buried to depths of from 200 to 300 feet and sometimes even deeper still.

But at last there came a change, and the outbursts of the grand volcanic epoch of the Sierra Nevada announced the end of the gravel period. And yet, the western slope of the Sierra was never flooded with liquid fire. On the contrary, true lava streams are among the rarest of the phenomena to be found there. The Tuolumne County Table mountain is the most noted and conspicuous instance of an extensive lava flow within the limits of California. But aside from this stream there is not, so far as I know, another noteworthy instance of the kind to be found on the western slope of the Sierra, between the Tuolumne and Feather rivers. Immense as is the quantity of volcanic materials spread over this region, it is all fragmentary in its character, and nearly all of it has been transported and distributed through the agency of water. It consists of all sorts of volcanic debris, from beds of the finest ashes and volcanic mud up to the coarsest breccias and conglomerates, which often contain boulders of many tons in weight.

The method in which the volcanic agencies put an end to the gravel period, was simply by flooding the whole country, over which the gravels had previously been accumulating, with successive flows of volcanic muds and debris of all sorts. But this was not accomplished all at once. On the contrary, it was a gradual process and occupied a very long period of time.

In proof of this, there may be here and there found (as for example, near Placerville) heavy beds of true volcanic gravel, i. e., of gravel in which nearly all the pebbles consist of volcanic rocks, but are as completely smoothed and rounded by water as any of the pebbles in the auriferous gravels themselves, thus showing that time was afforded for streams to wear the rocks and manufacture gravels. Again, it is not rare in some parts of the country to find that, long after the commencement of the volcanic period,

a bed of true auriferous gravel, derived from still uncovered bedrock somewhere higher up in the range, has spread itself extensively over the top of heavy masses of previously accumulated volcanic materials, and then been subsequently buried by still far heavier masses of similar volcanic origin.

It is probable that during the latter part of the volcanic epoch the discharges became heavier and more frequent, affording less and less opportunity for running streams to work uninterruptedly, and producing heavier and heavier floods of volcanic breccias, muds and ashes.

But, at last, the volcanoes died, and then the modern streams began their work.

The surface of the country, however, was greatly changed. The ancient gravels were now buried to depths ranging from 100 feet, or less, to 1,000 feet or more beneath a mass of volcanic detritus, which spread in an almost universal sheet of varying thickness from the crest to the foot of the mountain range, and even to some extent into the valley of California. As a general rule the thickness of this volcanic sheet decreased from the crest of the mountains towards the valley, and there were undoubtedly considerable areas here and there among the foothills which were never covered by it. Also in the regions of middle altitude there were occasional old bedrock hills and peaks which projected above its general level, and were therefore never entirely covered by it; such, for example, are the bedrock hills already referred to on the divide between the south and middle forks of the American river, above Georgetown, in El Dorado county. But even in the middle parts of the western slope, and still more in the higher parts of the range, all the lower portions of the country were deeply buried. Throughout the basin of the middle fork of the American river, the depth of this volcanic capping ranged from 300 to 800 feet, and places can be found nearer the crest of the range where its depth reaches from 1,500 to 2,000 feet.

It is easy now to understand how the higher ranges of bedrock hills originally scattered here and there over the western slope, and whose tops still projected above the volcanic capping, should serve, wherever they occurred, as in the case of the range already twice mentioned, on the divide above Georgetown, to mark and determine the outlines of the larger drainage basins of the new system, precisely as they did in the case of the old. It is also easy now to see how the Calaveras County "Bear Mountain" ridge has served as a complete barrier, not only to the ancient gravel streams themselves, but also to all the subsequent floods of volcanic matter, so that neither volcanic matter nor ancient gravel can now be found among the foothills southwest of this range, though they are plenty to the northeast of it, and also among the lowest hills about the Calaveras and Stanislaus rivers, at both ends of the range. The reason is precisely the same which caused both these rivers, which drain the country back of this range, to flow around its ends instead of cutting through it, viz., it was too high for them to surmount.

As a general thing the surface of the country at the close of the volcanic period was far smoother, and approached much more nearly to a plane surface than it did at the commencement of the gravel epoch, or than it had ever previously done. A most striking illustration and unquestionable proof of this fact still remains visible to anyone who has opportunity to examine it in the basin of the middle fork of the American river.

A magnificent view over the top of this whole basin can be obtained from the summit of a peak called Bald mountain, near Canada hill, in Placer county. This peak is some 5,000 or 6,000 feet above the sea, and from its summit the basin of the middle fork looks precisely like what it was in reality at the close of the volcanic epoch, namely, like a broad, smooth and gently sloping plain, over which one might easily drive anywhere with a carriage and four, were it not for the timber which covers it. The cause of this appearance is, that time enough has not yet elapsed for the degradation of the ridges which exist between the present streams, and that the crests of most of these ridges still rise to just about the level of the ancient surface-plane, while none of them rise above it, except the outer hills which form the circumference of the basin.

But to one who has actually traveled through this basin, and knows what a perfect labyrinth of tremendous canyons it really is to-day, the impression of such a view is one never to be forgotten, and the connection between the remote past and the present time seems strangely close and intimate.

Over the top of this smoothly sloping plain of loose volcanic debris, the new streams at the close of the volcanic epoch were obliged to find their way.

They ran at first almost at random, their course being modified by the slightest inequalities of the surface. But the general southerly grade was a steep one for rivers, and the materials were then very loosely compacted if at all, and the streams soon began the work of excavation. After a time, they had cut their beds deep enough into the volcanic detritus to restrain even the heaviest floods within their banks, and from that time on, the work proceeded with greater rapidity and power. At last they reached the buried auriferous gravels, and then the solid bedrock beneath them. But, by this time, they were already running in sharp V-shaped canyons from 300 to 500 feet or more in depth. They were subject at times to heavy floods, and at such times transported

vast quantities of debris, and of course they began at once to eat their way into the rocks themselves. From that time to this, under varying conditions of climate, etc., the process has continued, resulting in the formation of the modern canyons, which often range from 1,500 to 2,500 feet in depth,—of which depth, usually more than two-thirds, and oftentimes more than three-fourths, is excavated in the solid bedrock beneath the ancient gravels.

Such is the general outline of the history of the ancient auriferous gravels, which constitute the hydraulic mines and the "drift diggings" of California. But the complex and intricate details of that history will never be fully unraveled by man. Where the accumulations of these gravels were great and deep, and where the volcanic capping has been subsequently removed or was never very thick (or, as is probable at some localities, never existed at all), there we find the great hydraulic mines. Where the gravel was shallow, but rich, and was covered by a heavy mass of volcanic materials which has never since been removed, there we have the "drift" or "tunnel diggings."

I cannot here present the facts and the overwhelming evidence to sustain a great portion of what I have said, for the simple reason that such a presentation would require a volume.

I will, however, before I close state some of the evidence which goes to sustain the important proposition that the bedrock of the western slope of the Sierra Nevada has not been subjected to any considerable change of altitude since the gravel period. The considerations, which I shall here present, are three in number:

First, it is difficult to believe, and in the absence of positive evidence, it is extremely improbable, that a great mountain range like that of the Sierra Nevada, which in the course of its previous upheavals has been so thoroughly crushed and shattered in all directions, should in this later stage of its history have undergone any considerable change in its altitude from the action of subterranean forces of any kind whatever, without the occurrence of numerous local faults and disturbances of various kinds, which if they had taken place since the deposition of the gravels, must necessarily have produced corresponding disturbances in the gravels themselves. But the fact is that anything like faults in the gravels, or appreciable local disturbances of any sort in the bedrock underlying the gravels since the deposition of the latter, are among the rarest occurrences to be found in the gravel region.

I have, indeed, seen such things, and I always watched for them. But among all the hundreds (and more probably several thousands) of miles of my travels up and down in the gravel region, I never saw more than half-a-dozen such cases, and several even of these few cases were very indistinct and uncertain in their character. By far the best marked instance of the kind which I ever saw was at Yankee Jim's in Placer county. There was here a distinct and unmistakable fault cutting both the bedrock and the overlying gravel. It involves a sharp displacement, or jump, of from 12 to 15 feet, and could be traced for several hundred yards, across the hydraulic ground. But even this was far inferior in extent and general magnitude to some of the disturbances caused in Owen's valley by the single earthquake of March 26th, 1872, which, among other things, produced a single fissure or fault which I saw in the summer of 1873, and which could then be traced for 20 miles along the western side of the valley, and which at many localities involved a displacement of from 15 to 20 feet.

Second, if any notable elevation of the range as a whole had taken place since the gravel epoch, then the present lowest foothills of the range must necessarily during that epoch have been submerged beneath the waters of an inland lake or sea, and in that case there would certainly have been formed upon them extensive lacustrine or marine deposits, some portion of which would have remained until the present time. But the fact is, that no trace of any such deposits can be found from the moment we strike the bedrock foothills.

Third, the mode of distribution of the gravel and volcanic detritus along the edge of the great valley itself, is an almost absolute proof, not only of the assertion that there has been no considerable disturbance of this region since the gravel epoch, but also of the additional fact that the larger streams of that ancient epoch found their exit from the mountains into the valley at almost precisely the same localities as do the larger streams of to-day. For these materials occur in large quantities along the edge of the valley, almost exclusively in the immediate vicinity of the *débouchements* of the larger modern streams, such as the American, the Cosumnes, the Mokelumne, the Calaveras, and the Stanislaus. Moreover, the distribution and present structure of the materials at these localities is not of the kind that would have existed if they had been deposited beneath the waters of a lake or a sea, but is precisely what the action of flowing streams in open air is calculated to produce.

I will close this paper, already longer than I intended to make it, with the single additional remark, that if any one desires further and more convincing proofs of the propositions which I have advanced, I must refer him, first, to such portions of my report upon the gravel regions as are embodied in Prof. Whitney's writings; and, second, to the country itself, which will undoubtedly remain subject to examination for some time to come; being well satisfied that the results of future careful inves-

tigations, whatever additional light they may throw on many of the difficult questions connected with this subject, will only serve to confirm the conclusions herein advanced, so far as those conclusions go.

USEFUL INFORMATION.

HINTS CONCERNING SAWS.—A saw just large enough to cut through a board will require less power than a saw larger, the number of teeth, speed, and thickness being equal in each. The more teeth, the more power, provided the thickness, speed, and feed are equal. There is, however, a limit, or a point where a few teeth will not answer the place of a large number. The thinner the saw, the more teeth will be required to carry an equal amount of feed to each revolution of the saw, but always at the expense of power. When bench-saws are used, and the sawing is done by a gauge, the lumber is often inclined to clatter and to raise up the back of the saw, when pushed hard. The reason is that the back half of the saw, having an upward motion, has a tendency to lift and raise the piece being sawn, especially when it springs and pinches on the saw, or crowds between the saw and the gauge; while the cut at the front of the saw has the opposite tendency of holding that part of the piece down. The hook or pitch of a saw-tooth should be on a line from one-quarter to one-fifth the diameter of the saw: a one-quarter pitch is mostly used for hard, and a one-fifth for softer timber. For very fine-toothed saws designed for heavy work, such as sawing shingles, etc., even from soft wood, one-quarter pitch is best.

GRINDSTONE SPINDLES.—Common grindstone spindles, with a crank at one end, are open to the objection that the stone will never keep round, because every person is inclined, more or less, to follow the motion of his foot with his hand, which causes the pressure on the stone to be unequal. The harder pressure is always applied to the very same part of the stone, and will soon make it uneven, so that it is impossible to grind a tool true. To avoid this, put in place of the crank a small cog-wheel to the spindle, say with twelve cogs; have another short spindle, with a crank and a cog-wheel of thirteen cogs, to work into the former. The stone will make about 0.07 of a revolution more than the crank, and the harder pressure of the tool on the stone will change to another place at every turn; and the stone will keep perfectly round if it is a good one.

REMOVING OBSTINATE GLASS STOPPERS.—The obstinate sticking of glass stoppers in bottles is a constant source of trouble, not to say of profanity, in the laboratory, and many methods of loosening them have been suggested. These are all useful, though each of them fails in certain cases, and another has to be tried. The following, given in the *English Mechanic*, will be likely to answer the purpose when the shape of the stopper and of the neck of the bottle admit of its use: "Take two pieces of wood, put them between the neck of the bottle and the lower part of the stopper. Having fixed them securely by a piece of string, soak the whole affair in water, say ten hours; if the wood has not swelled enough, then pour some hot water over the wood, and as it swells (which it must) out comes the stopper."

STAINING PINE.—The *Northeastern Lumberman* recommends the following manner of staining pine to present black walnut: Put pulverized asphaltum into a bowl with about twice its bulk of turpentine and set where it is warm, shaking from time to time until dissolved; then strain and apply with either a cloth or a stiff brush. Try a little first, and if the stain be too dark, thin it with turpentine. If desirable to bring out the grain still more, give a coat of boiled oil and turpentine. When the wood is thoroughly dry, polish with a mixture of two parts shellac varnish and one part boiled oil. Apply by putting a few drops at a time on a cloth and rubbing briskly over the wood.

TO PREPARE PURE NITROGEN.—Mr. W. Gatehouse, in the *London Chemical News*, states that when ammonium nitrate is heated with manganese dioxide (black oxide of manganese) the mixture rapidly assumes a red heat. But if the temperature is kept down as much as possible, to about 180° C. (=356° F.), pure nitrogen is given off, according to the equation: $4\text{NH}_4\text{NO}_3 + \text{MnO}_2 = \text{Mn}_2\text{NO}_3 + 8\text{H}_2\text{O} + \text{N}_2$. Three grams each of ammonium nitrate and manganese dioxide yield 630 cc. of nitrogen in practice, which is nearly the theoretical quantity.

TEST FOR MERCURIAL VAPORS.—As a reagent much more sensitive than gold-foil, M. Merget, of Bordeaux, recommends paper steeped in an ammoniacal solution of nitrate of silver, or in chloride of palladium. This test paper is so sensitive that although a slip of sheet copper, plunged into a liquid containing one part of mercury in ten thousand, remains bright after immersion, when exposed to the ammoniacal silver paper it occasions a characteristic black spot. Mercury, even when solidified by cold, emits vapors in quantity appreciable by the reagent.

GOOD HEALTH.

Blistering as a Remedy.

Dr. H. S. Anderson, in his recent "Harveian Discourse," published in the *Edinburg Medical Journal*, speaks as follows of the uses of blistering:

Another remedy, which I fear is somewhat unduly neglected also, is counter-irritation by means of blistering; and I think I have observed in some young practitioners an approach to something like terror when blistering is spoken of as a remedy that may frequently be used. Certainly, as regards children's diseases, there is more of this fear than there should be. It has frequently, for example, been my experience to see children, in consultation with a younger practitioner, when blistering in acute head affections had never been dreamed of. In nearly all acute inflammatory affections of the brain, tubercular or not, in children, I am strongly of opinion that after shaving the head the application of blistering fluid has a most rapid and satisfactory effect. Inflammatory attacks also of the peritonsillar and chest in children are often controlled by blistering, although the size of the vesicator and the length of time applied must be carefully considered. And in the rheumatic affections of the joints in adults repeated blistering has often the happiest results. For many chronic conditions, also, counter-irritation has always held a high place in my list of remedies. In chronic tubercular affections of both chest and abdomen I think occasional and repeated blistering is frequently beneficial, and also in chronic and obscure head and other affections of the nervous system. For example, in blister over the roots of the nerve in herpes zoster often relieve the neuralgic pain so generally present, and often so difficult to get rid of. In diphtheritic paralysis, also, blistering the nape of the neck, and even down the spine, often expedites cure in a wonderful way. In the uterine or ovarian pain so often complained of on the left side there is no better remedy, sometimes, than a succession of fly-blisters, and the tenderness of epinal irritation is frequently relieved, if not got rid of by the same means. In chronic effusions the use of blisters is still fully acknowledged, and do not, therefore, call for special mention.

ANTAGONISTIC AGENTS.—*Morphia*.—The antagonistic action of morphia and ntipropia upon respiration is brought out in strong contrast, and attention is called to the similarity of their action upon the reflex mechanism. In the coma of opium sleep or poison there is a low blood pressure, while the delirium of belladonna poison is due to the high blood pressure, induced by this agent. It is suggested that belladonna will enable the centers to continue in action under large doses of morphia without marked interference with the action of the latter upon the cerebral spinal centers. *Strychnia*.—This agent exerts a powerful influence over poisonous doses of chloral, and chloral exerts even a greater power in counteracting the toxic effects of strychnia. From this fact it is argued that strychnia stimulates respiration, and the author recommends its use in chronic bronchitis, emphysema, etc., especially as it is also known to act as a cardiac stimulant. Dr. Fothergill considers strychnia superior to digitalis as an antidote to aconite.

POISONOUS CLOTHING.—The aniline dyes now extensively used ought to be employed with caution, since it appears they may render wearing apparel poisonous. There have been a large number of cases reported from various sections of the country of children having their legs poisoned from wearing colored stockings. A sad case is reported from Hartford, the victim being a young lady of that city, who has had her face seriously poisoned from a new blue veil, which, when examined by a chemist, was found to contain a large quantity of aniline dye. This dye is obtained from coal tar, which is a residuum obtained in the manufacture of gas from coal.

A NEW ANÆSTHETIC.—The Paris correspondent of the *Lancet* gives some particulars of Prof. Bert's new method of producing anesthesia. A mixture of 85 parts of nitrous oxide and 15 parts of oxygen was inhaled by a patient under increased atmospheric pressure. The experimenters were subject to the same pressure, but it was not sufficient to cause serious discomfort. In about 15 seconds the patient was completely insensible and the muscles relaxed. Dr. Labbe then operated for ingrowing toe nail, and the patient recovered consciousness in less than a minute after the anesthetic was withdrawn. Under ordinary pressure the mixture does not produce any anesthetic effect.

THE DEATH-RUN.—An eminent English surgeon states, on no account, except that serious fire was on hand, or to save a life, should any person ever run after having reached 50 years of age. The reason alleged was, that a tendency to heart disease, apoplexy, etc., might suddenly be brought to a climax by violent exertion, and especially with corpulent persons. Mr. William Adamson, aged 56 years, residing at Germantown, Pa., lately ran a considerable distance to reach a train of cars and fell dead. A post-mortem examination showed that he died of heart disease.

Business Announcements.

Annual Meeting—Syndicate Mining Co.
 Delinquent Sale—Gover Milling and Mining Co.

The Week.

This week has been characterized by favorable indications from a mining and manufacturing point of view, as well as by the infallible signs of a revival in the business community. The prospector is meeting with his merited reward in the speedy development of mining interests in the whole Rocky Mountain region. Aside from an occasional exaggerated account of some "fud" in Arizona and Utah, the mining operations of this region have developed into a steady money-making business, displayed visibly by the streams of bullion flowing from every quarter. Some old claims are being hought up by capitalists, who are making preparations to derive a good income from the investments. Speculative prospects are very little regarded, and it seems as if the day of "paper" mining has gone forever. Judging from a variety of information, the clouds are gradually breaking and the sun of prosperity is shining upon us, to warm us into unwonted vigor. The Holway process in another column seems to be worthy of investigation in the economical treatment of sulphurets, etc. The foreign scientific and mining journals have deemed it worthy of an extensive notice. The origin of auriferous gravel deposits and mineral veins is being closely investigated—with what results may be better determined at some future day. Old theories seem to be revived or carefully compared with the results of recent discoveries. There is more unanimity in the scientific researches now being made, and the various geological questions which have arisen from the anomalies of the Rocky Mountain region are nearly ripe for solution. In nothing does this coast shine more than in the wisdom of our mining laws, if the Eastern mining press is any criterion. The East is called upon to copy a system as a nearly perfect one, which but a short time ago was derided as full of imperfections, and the uncertainty of Eastern mining requirements has driven capital in our direction. With regard to inventors, the courts are basing their rulings upon broader grounds than the mere diota of the hooks. Altogether, the week indicates the inauguration of an era of common sense progress.

A New Metallurgical Process.

We took occasion in another number to mention the Holway process of utilizing sulphides as fuel. The process is exciting the attention of metallurgists in Europe, but so far as we have been informed very little attention has been given to the matter in the United States, particularly on this coast. The ores suitable for use in this process are so abundantly distributed over all parts of this coast, and the process itself seems to be so well based upon large, practical experiments, that it may be of great importance as regards the economical extraction of gold and silver. From the experiments it appears that copper, gold, silver and nickel are all extracted with equal ease, and when we consider that a very small mine output is regarded as a paying investment in Great Britain, the value of the process is enhanced by the statement in the *Mining World* that it may increase the value of many mines now almost valueless. The consumption of fuel in all of our metallurgical operations is vastly in excess of the theoretical limit, and much inquiry has been devoted to its economization. The causes which militate against perfect economy lie, perhaps, in the misunderstood or misapplied elements of nature. We know by practical every day experience that an excess of fuel in a furnace smotheres combustion, and that only a well regulated supply, sufficient to maintain an equable degree of temperature, is proper. Yet we introduce into our furnaces an excess of oxygen only a portion of which acts upon the material to be burned, or the oxygen is not brought in contact with the combustible matter with sufficient rapidity to obtain the required temperature for the operation, and the oxidation of the substance is incomplete. Again, the various gases generated are suffered to pass off hot or unconsumed. In the Bessemer process a high point of utility has been reached. By blowing air through molten crude iron a very high temperature is attained by the combustion of small quantities of carbon and silicon contained in the crude iron. But the Bessemer process is still open to the objection that the carbon is only partially consumed, and a large amount of heat escapes with the carbonic oxide and nitrogen.

The theory of the new process is as follows: When thin streams of air are forced through molten sulphide of iron, lying on a tuyere hearth, a high temperature is produced by the perfect combustion which ensues in the midst of the sulphides, and no unburnt gases, excepting nitrogen and sulphur vapor, escape from the surface of the molten mass. The hot nitrogen and sulphurous acid may be forced to act upon iron pyrites and other mineral matter obtaining molten protosulphide, which is subsequently burnt by the oxygen of the air driven in at the lower part of the furnace, thereby producing the heat necessary for continuing the operation. It is, in fact, a system of fractional oxidation, in which the numerous constituents of a complex furnace charge can be separated from each other, and concentrated in different parts of the apparatus, the heat necessary for the operation being obtained by the combustion of a portion of the less valuable constituents.

Gold and silver do not oxidize under the same conditions as other metals, for which reason in supplying air to the ores of these metals, the iron is the first element to suffer oxidation, so that if the oxidation be arrested before the whole of the iron has been burnt, the cobalt, nickel, copper, silver and gold present will be found in the unburned portion. The same principle exists in the Bessemer process of treating pig-iron for the manufacture of steel, in which a current of air is caused to hubble up through a bath of molten crude iron. The silicon is first oxidized, and is followed by the carbon until the whole of the silicon and carbon have been burned out of the molten material. Even in the more volatile metals the process has been employed. A. H. Allen of Sheffield, by it, has obtained metallic antimony simply by the oxidation of sulphide of antimony. This is the substance of Mr. Holway's process which has been the theme of much comment in European scientific journals. One of its chief merits is the claim that it is equally applicable to the very poor as to the very rich ores, for however small the resulting regulus, it will contain nearly the whole of the silver and gold present in the furnace charge, while any lead, zinc, antimony and arsenic will be obtained as sublimate.

It is also claimed, as is evident from the description, that it will almost entirely obviate the necessity for using carbonaceous fuel, at least so far as the production of a regulus is concerned. *Nature* says, "one of the chief practical questions connected with this process is how far it may be trusted to effect the smelting of ores containing moderate proportions of sulphides." We believe the supply might be increased by adding pyrite, as there is no danger from an excess.

The whole process seems to be the obtaining of gold and silver, as well as other metals through concentration and separation in the form of metallic regulus, by a process analogous to destructive distillation.

A DEFICIENCY of over \$20,000 has been discovered in the funds of the county treasury of Santa Cruz, and the Treasurer has been placed under arrest.

Patentees and the Government.

Many cases have arisen under the Patent laws in which a patentee has sought to recover damages from the Government for the infringement of his patent right, and it has always seemed a hardship for inventors to suffer a sacrifice of the exclusive privileges granted in their letters patent through the violation thereof by the power which created and granted the right. Decisions of the United States Courts have heretofore seemed to concede the abstract right of the inventor to damages against the Government for infringement, but considered it in the light of a *damnum absque injuria*, inasmuch as a remedial action could not be enforced against the United States. A case, however, has lately been decided by Judge Wheeler in the United States Circuit Court for the Southern District of New York which, while recognizing the doctrine of impeccability of the Government, indicates a way by which patentees may enforce their rights against violations under Governmental authority.

The suit was brought by the owner of a patent granted in 1863 to Marcus P. Norton for an improvement in marking and cancelling stamps for postoffice use. The device diminished the time for stamping letters by about one-half, the machine cancelling the stamp and imprinting the post-mark at a single stroke. There is no demand for such an invention, however, except for postal purposes, hence when the owner of the patent found that the postoffices persisted in using the machine without paying royalty, he discovered that his invention was in danger of becoming valueless.

This suit was brought directly against Postmaster James for infringement, and required him to account for profits realized from his use of the invention in the New York postoffice. The defense of chief general interest was that the postmaster, in using the stamp, acted as an officer for the Government, and only for its benefit; and that the monopoly granted by a patent does not extend to or prohibit use by the Government. As to this point the opinion says:

"But the exclusive use of the invention granted to the patentee is property, and this property is now owned by the plaintiff. The grant saved nothing for the use of the Government; it was exclusive absolutely throughout the United States. It was granted by express law of Congress, pursuant to the Constitution, without which it could not exist. But all property is upheld by law, either expressly or impliedly enacted or adopted, all of which is the law of the land, the same as the statutes upholding patents are. This property, like all other private property recognized by law, is exempt from being taken for public use without just compensation by the supreme law of the land. Nor can it be taken by any officer at will, in time of peace, leaving the owner to seek compensation. The property in a patented invention stands the same as other property in this respect."

The courts have agreed that though English patents are probably subject to a right of the Crown to use the invention, yet under our patent law no such reservation is implied; the United States has no better right than has a private person. But familiar principles forbid the courts to enjoin the Government directly, the chief obstacle being that although the court can render judgment against the Government for money it has contracted to pay, it cannot for damages for wrongs done by its officers.

Under Judge Wheeler's decision, a patentee may claim profits from the officer chargeable with infringing. The doctrine has support from a decision of the Circuit Court in Massachusetts, about two years ago, where infringers made defense that their use of the invention was not for their own benefit, but to fill a contract with Government, and for its use; but the court said this was no protection—Government could not authorize them to violate patents. And it is consonant with justice. In the whole function of forwarding letters, Government acts only as a business agent of the masses of the people; and if they, as individuals, have not the right to use an invention free, their agent the Postoffice Department, should not be allowed to do so. The same principle obtains in other branches of the business of the Government.

EUROPEAN INVENTIONS IN JAPAN.—A singular outcome of the policy of the British government in opposing international patent and copyright laws, so often urged upon it, has recently been developed in Japan. It appears that a well known firm in Nagasaki recently imported a Jordan's patent rock-drill for use at Inakasma, where blasting is constantly going on, but no sooner did the officials at the Government works at Akenoura hear of its arrival and its excellent results than an exact copy was made, which may now be seen in the Nagasaki exhibition. The Japanese specimen is excellently made, and reflects credit on those who undertook the work, but the higher question of infringement of foreign patents is one which may fairly occupy the attention of Ministers. The last sentence means "homarding" the ports of Japan to obtain damages for the infringement of a patent. It is urged upon Japan by the English journals that "if she wishes to hold her place among the advanced nations of the world, a guarantee will have to be given that foreign inventors shall meet with that honesty to which their genius and labor entitle them."

Chrome Mines of San Luis Obispo.

The chrome mines of San Luis Obispo county seem to be attracting considerable attention, and from information gathered through the *Tribune* we infer that the ore deposits are extensive enough to justify the erection of reduction works. The principal mine, the "London," was accidentally discovered by two parties while on a hunting excursion in the fall of 1877. It is located about five miles north of San Luis Obispo, and is now being worked. The peculiarity of this location is that the chrome is not a surface deposit as is usually the case, but exists in an extensive stratum or vein. Work was commenced by running a tunnel into the hill on the west side 75 or a 100 feet, when the ore was struck and some 400 tons taken out; when, owing to the negligence of the miners a cave occurred, which for the time being put a stop to operations. The owners of the mine then concluded to tap the hill on the south side. Accordingly a contract was made with a party, who ran a tunnel in about 100 feet; but failing to strike the ore, the contractor became discouraged and abandoned the work when, as was subsequently demonstrated, he was within eight feet of the deposit. A third contract was entered into with Mr. Benitz, an experienced miner, under whose supervision the work is now progressing satisfactorily. There are two tunnels in the hill, one about 40 feet above the other, and they are in about 125 feet. These tunnels are connected at the extreme end by a winding, irregular shaft or chamber, from which the ore is taken. For a distance of about 50 feet from the entrance of the tunnels the rock is firm and no timbering is required. Beyond that point, however, the rock is soft and crumbling, and necessitates timbering. The timber used is procured near at hand. In the lower tunnel a track is laid, and a small car is used to carry the ore to the "dump." The shaft connecting the tunnels is through an immense body of ore, which appears to be of the finest grade. The superintendent of the works says there is more chrome in the mine than can be taken out in 10 years. They are now extracting about 20 tons per day with the labor of six men. It is claimed that about 4,000 tons, of 2,240 pounds have been taken out of the London mine. The average price received has been about \$7 per ton.

Although the latter mine has as good prospects as any other mine it is not the only one producing largely. There are said to be at least a dozen in the district which are now yielding large quantities of ore. The Trinidad particularly has been worked constantly for nearly two years, and the estimated yield several thousand tons. Other mines are yielding very rich ore, the average assay of some being as high as 50%. The total output cannot be stated with certainty, because some of the mine-owners are not inclined to make known their product. Besides the organized mines considerable chrome has been taken out of small deposits by individuals in various localities. A fair estimate, however, would place the total output for the last two years in the neighborhood of nearly 22,000 tons. The average price for the ore is \$7 per ton. Many claims, however, are not now being worked, because the prices offered for the ore will not pay the expense of mining. With the contemplated reduction works in operation it is claimed the ore would bring from \$18 to \$25 per ton.

The Sierra Mojada Mine.

The mineral wealth of Mexico is to a great extent still unknown. The advantages for prospecting are not as favorable as in the more settled regions of the United States. Immensely rich ancient mines, which are known to exist from their mention in old records, are eagerly sought for. The Indians know more than they are willing to tell, knowing perhaps the fate of their ancestors when the gold hunters arrived. Rich mines have recently been found in the Sierra Mojada by a Mexican Lieutenant and squad while in search of Indians. The San Antonio *Express* thus mentions the find:

Believing that the Indians had their share in the rough and almost unapproachable region, the Lieutenant proceeded to investigate, and came upon several squaws and children, and two worn-out warriors, molding bullets. The reds were taken in tow, when the cave was searched, and quite a quantity of silver bullets and other roughly made silver articles were found. So astonished was the Lieutenant to find the precious metal put to such a common use that he made further search, discovering the very locality at which they obtained the ore. Their mining tools consisted principally of two or three old hatchets and axes, with which they cut the ore loose as it clung, an almost solid mass, to the side of a gigantic mountain. For years the Indians have visited many Mexican towns, even going as far as Monclova, with cargoes of bullets of pure silver, which they almost gave away. But no one knew anterior to the discovery made by the Mexican Lieutenant above referred to, where they manufactured the bullets. Now, the locality is swarming with seekers after wealth, and the richest silver discoveries known have been found.

New Electric Mining Lamps.

A late number of the *Colliery Guardian* gives a long account of Andre's electric mining lamp, claiming its great desirability in mining operations, sub-aqueous works, and in factories where explosive agents are dealt with.

The light is enclosed in a strong glass cylinder, apex only at its lower end, which rests in an air-tight seating upon the base of the lamp. By this means the atmosphere is securely excluded, and explosions of fire-damp certainly prevented. The cylinder is protected by rods on the outside; the lamp is constructed to be suspended from these rods, and the latter are utilized to pass the electric current in to the carbons. Being thus complete in itself, the lamp, when not in action, may be easily carried about from place to place, and suspended at any point required. The lamp consists essentially of four small carbon rods or pencils, enclosed in a series of vertical tubes. A light weight in each of these tubes above the carbon rod forces the latter down as its lower end is consumed. This weight is not heavy enough to break the point of the carbon, even when the point has become very fine, so that no unpleasant flickering occurs as the carbon descends, and no waste is occasioned. The arrangement of the carbon rods and the weights in tubes obviates the necessity for the strings required in other electric lamps working on the same principle of incandescence. The lower ends of the carbons rest upon discs of copper, which constitute the negative poles. The metal being combustible, only one pole, the positive, is burned away. When the current is impeded by the accumulation of silicic acid from impurities in the carbon the disc turns slightly, and the point of the carbon sweeps the impediment away; and should the carbon rod fail to descend, by sticking in the tube, the disc rises and breaks it away from its point of contact.

The glass cylinder being air-tight, the combustion of the carbon is retarded through lack of oxygen, and finally ceases altogether. Practically, however, a slow waste occurs, due, perhaps, to oxygen occluded in the carbon, or possibly by the disintegrating action of the electric current. When the first carbon rod has been consumed, or if from any other cause it becomes extinguished from an interruption of the circuit, the current passes automatically to the second of the series. This rod is then slowly consumed, like the latter portion of the first. From the second, the current passes in like manner automatically to the third of the series, and from this again to the fourth. The total duration of the four carbons, which are each 9 inches in length, varies from 500 to 600 hours, according to the strength of current used.

There is no risk of the lamp being extinguished, because, in case of an interruption, the automatic action of the commutator switches the current from one carbon to the next in the series. The intensity of the light is about 75 candles. The light is regarded of great importance, in consequence of its superiority and the non-vitiating and non-heating of the atmosphere of the mine. It also works well under water, in works where caissons are used.

Our Resident Arizona Agent.

Capt. W. H. Seamans, our agent in Arizona, has his residence at Tucson. He will, however, make occasional trips into other parts of the Territory. Capt. S. will correspond for the *PRESS*, and solicit items of mining news and discoveries. We hope our readers in that part of the country will assist him as far as they can in furnishing information and increasing the circulation of the *PRESS*. We have faith that Arizona will in time develop even more wonderful mineral wealth than it has yet done, and that its mining interests will in the near future rival those of older settled communities. We desire to assist these developments by spreading a knowledge of the resources of the Territory, among that hardy class of prospectors and miners who make such a country. We wish also to call the attention of our men of capital to the wealth which now lies hidden within its borders, needing only their slight assistance to be rendered available. We have therefore requested Capt. Seamans to act as Territorial agent for the *PRESS*, and to furnish us with all the information possible concerning the mineral resources of the country.

A PIONEER'S WORK.—We have received from the author, Rev. Albert Williams, an interesting work having for title "A Pioneer Pastorate and Times," embodying contemporary local transactions and events. Mr. Williams arrived in California in 1849, and became the founder and pastor of the First Presbyterian Church of S. F., the pioneer Protestant Church organization. The book is a pleasant narrative of matters that fell under the personal observation of the author, and is a book which when commenced gives in interest as each historical fact of California incidents approaches the California of to-day. We are charmed with the work.

Composition of the Iowa Meteorite.

On the 10th of last May a meteorite fell at Estherville, Emmet Co., Iowa, about 5 P. M. Its fall was attended by a terrible explosion, resembling the discharge of a cannon, only louder. Numerous succeeding explosions were heard, and to an eye-witness the track of the meteor appeared like a red streak in the heavens, passing from west to east. The mass penetrated 14 feet below the surface, and weighed 431 pounds. It measured 27 inches in length by 22½ in breadth and 15 in thickness. Its surface is described as "fearfully rough," with ragged projections of metal. Several smaller masses, varying in weight from one to eight ounces, were found in the immediate vicinity.

Prof. Shepard, of Amherst college, in a description of this meteorite, says that it is marked by the unusual prevalence of chrysolite and meteoric iron, the former constituting two-thirds its bulk; also by the size and distinctness of the chrysolitic individuals, which are of a uniform yellowish gray or greenish-black color. It is highly crystalline and difficultly frangible. There are no traces of decomposition; on the contrary, it is throughout a fresh, undecomposed crystalline aggregate. The stony portions nowhere present traces of oolitic or semi-porphritic structure, so common in meteoric stones.

A very remarkable appearance is exhibited by the meteoric iron in some of the specimens. It is the bright, silvery whiteness of the metal where it forms a portion of the exterior of the stone. It appears to have been fused, and is surrounded on all sides by the black crust, coming from the stony material. It will be interesting to know whether this character prevails over the main mass from which these fragments were separated. If such should be the fact, it would give us a second case in which meteoric iron, seen to fall, reached the earth in the possession exteriorly of a high metallic luster. The other instance is that of the Dickson County meteorite, Tennessee, July 30th, 1835.

The next most conspicuous species present is troilite. This also is in distinct individuals,

IMPROVED FUSE CUTTER AND NIPPERS.

sometimes as large as a pea. It is highly crystalline, rarely presenting splendid crystalline facets, whose color approaches silver-white. The proportion in which it exists is apparently large, and may equal 2%.

Next in importance comes the feldspathic mineral, presumably anorthite. It is highly crystalline, white, lustrous and nearly transparent, resembling in these particulars the similar mineral found among the ejecta of Vesuvius.

Among the specimens are two very distinct examples of an opal-like mineral of a yellowish-brown color, which I take to be chassinites. Its luster is resinous, structure imperfectly slaty, to massive and couchoidal. A small granule of chromite occurs in one of the fragments of the massive chrysolite.

Judging from specimens in hand, Prof. Shepard thinks it cannot properly be referred to any group of meteoric stones with which we are acquainted. It would rather appear to be a connecting link between the litholites and the lithosiderites, though it may possibly find a place in the eucritic group of the former, in which case it would form an order by itself.

AURIFEROUS GRAVELS.—The paper on "The Auriferous Gravels of California," read at the last meeting of the California Academy of Sciences, and which we give in full on pages 182-183 of this issue, will be read with interest by our hydraulic miners. It is by W. A. Goodyear, formerly of the California State Geological Survey, and now Geologist of the Republic of Salvador. During his connection with the Geological Survey of this State, Mr. Goodyear studied closely the questions connected with our gravel regions, and publishes some conclusions in the paper referred to. And, by the way, in reading it, the word "something," in the sixth line of the third column, should be "sometimes," reading, "even sometimes directly northeast," etc.

A NUMBER of farmers have sailed from Liverpool for Canada, to investigate the advantages of settlement in the Dominion.

DAILY, the California champion, was defeated by Capt. Wehh in their swimming match at Coney Island last Sunday.

A REMARKABLE increase of Chinese has taken place in New York, Boston and Philadelphia during the past two years.

Combined Fuse Cutter and Nippers.

In firing charges of any of the high grade explosives, such as Giant, Vulcan or Safety powders, a very powerful cap is required. These caps contain a substance or substances which require pressure and confinement in order to be rendered effective. The ends of the caps are left open for the introduction of the end of the fuse or electric igniter, and the copper of the cap is then pressed or squeezed over the fuse so as to close the end tightly, and at the same time secure the fuse to it. The fuse itself is cut fresh when introduced in the cap. Ordinarily the cap is pressed over the fuse by biting the cap between the teeth, an extremely dangerous undertaking, but one commonly done by miners accustomed to use the cap.

The Safety Powder Company of this city have a combination implement, by means of which the fuse may be cut off, and the cap squeezed or pressed around it, the same implement answering both purposes.

It is formed somewhat in the shape of an ordinary pair of pliers, as the engraving shows. The head of the tool is formed with a pair of angular cutting blades, *a*, by means of which the fuse is cut off square. In beveling off the heads to form the cutting blade, the heels are made so as to form a central notch on each side as shown, the upper part of each blade inclining outward from the top. This construction causes the two blades to form a sort of hook or grip, which prevents the pressure on the handle forcing the fuse out between the blades. In the shank of the implement are formed the jaws, *b*, in which is formed an edge which will not cut the copper or brass of the cartridge, but will squeeze it tightly around the fuse. After the fuse is cut and put into the open end of the cartridge the latter is inserted between the jaws, and by bringing the handles together the cartridge is tightly squeezed around the fuse.

The implement is stamped out of flat steel, light and strong, and may be carried in the pocket conveniently. The implement is particularly intended for use with the "Safety Caps," a new and important substitute for the sensitive and dangerous percussion caps in com-

mon use. The nature of the cap filling requires close confinement, and the copper of the cap has to be pressed firmly over the fuse, which this combined implement does perfectly. It was recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency by Gen. W. S. Rosecrans, President of the Safety Powder Company of this city.

Colorado State Geologist.

We were glad to receive a visit yesterday from J. Alden Smith, State Geologist of Colorado, who is in California on business and for information.

Mr. S. is of opinion that the mining industry of Colorado is rapidly assuming the condition of a steady paying business, free from great excitement. The discoveries that have been made are very satisfactory as convincing proofs of the wealth of the State. The carbonates are very rich, although many quite rich claims are not being worked because lead is worth nothing. It is claimed that in the Leadville region bullion to the value of \$800,000 per month is being turned out.

Speaking of the carbonates, Mr. S. says they exist in many places from 30 to 40 feet in thickness, yielding from 60 to 500 ounces of silver per ton. The carbonates are very soft and melt up like butter, the highest grade yielding 40% lead and about 50 ounces silver. The metals are run into base bullion, which is shipped elsewhere.

Several mines of telluride ores are being worked in Boulder county, two of which, the "American" and "Slide," are down about 500 feet, and producing largely. The value of third grade ore averages \$250 per ton. The veins are well defined, some of them being contact veins between porphyry and granite. Most of the fissure veins are in granite. Some rich veins are found in mica slate. The average thickness of the ore is 2½ feet. Mr. Smith goes from San Francisco to Grass Valley.

THE President of the Howard Association of Memphis is in New York, seeking aid for the yellow fever sufferers.

SIXTY THOUSAND workmen are affected by the trouble between the earthenware manufacturers and their men in England.

Peculiarities of Altitude.

A correspondent writing recently from Leadville to the *Grass Valley Union*, speaking of the effects of the great altitude of the place, which is 10,300 feet above the level of the sea, says that all fermented liquors intoxicate more quickly than at lower elevations. The boiling point, owing to the decrease of atmospheric pressure, is much lower than at San Francisco, and the alcohol is sooner vaporized and taken into the circulation, producing intoxication much quicker.

The boiling point of water here is about 190 degrees, instead of 212 degrees, the effect of which in boiling beans, eggs, potatoes, etc., is that it requires a long while to cook them in an open vessel, and it is necessary to keep the pot well covered or the water will vaporize and escape before being raised to the requisite degree for thorough cooking. At this elevation much air is required to fill and satisfy the lungs, and breathing must be quicker in order to properly oxygenize the blood. It is said, too, that after one has been here for some time the coloring matter of the blood becomes darker, being changed from the peroxide to the sesquioxide of iron. With a person suffering under any difficulty or disease of the heart the effect of any long-continued exertion is to cause a dangerous degree of palpitation, and even with persons entirely well the pulse runs extremely high.

There are other and notable facts connected with this altitude. There are few birds seen here—perhaps for the reason that flying is difficult in the light air. The common house-fly, the summer pest of our Eastern housekeepers, is unknown here. There are some of the outdoor blue-bottle variety, but they seem languid and tired.

Another result of the lightness of the air is that, having so little density, it is easily heated by artificial means. Our nights are uniformly cold—so cold that it is uncomfortable to sit without a fire; but a few pine chips or small sticks will warm an apartment very quickly. At the same time the sun's rays do not seem to have the heating power that they do in lower elevations. This seems to confirm the theory that there is no substantial caloric in the rays of the sun, but that heat is the result of chemical action, generated by the direct rays with the elements of the atmosphere—the directness of the rays and the density of the atmosphere. While standing high upon these mountains, even at a distance from any snow-drifts, and where the air is still, the summer sun has only sufficient power to make the air refreshing and pleasant, while those on the plains are sweltering under a torrid heat. In the shade of a rock or two it is always cool enough.

The effect of the altitude is the same as that experienced by balloonists, who in ascending from the surface of the earth, even on the hottest day, soon find it necessary to don their overcoats and warmest clothing. In the night, here, a good supply of blankets is always necessary, and nearly every morning heavy frosts are found, and sometimes thick scales of ice are formed. The crests of some of the mountains and many of the deep ravines upon their sides are still full of masses of snow so compact that one can walk over them without sinking. A day or two ago, in visiting a mine close to the summit of Mount Cross, I was compelled to cross a field of snow, hanging over the edge, which must have been a mile in length and probably in places twenty-five feet in depth.

A PROPER INQUIRY.—We call attention to the letter of John A. Church, M. E., of 115 Broadway, N. Y. We can assure our readers that the information is desired for scientific purposes only. The object in seeking the information is to settle the true status of milling as applied to gold ores. There is vast wealth yet undeveloped in our exhaustless mineral deposits, which needs only the requisite economical process to bring out. But there cannot be a satisfactory termination of the present difficulties in that direction without the combined assistance of a large number in furnishing information. Deductions may be correctly drawn from correct information founded upon the experience of many, whereas perfection of system may be long delayed by withholding the results of that experience. We hope that the desire of Mr. Church will be fully appreciated, and that everyone interested in this all-important matter will carry out his wishes as far as they are able.

COMETS IN SIGHT.—The *Rochester Democrat* says: Three comets are now visible in the northern heavens. Two of them are in the Great Bear, and not far apart. The second comet, discovered by Palisa, is very bright, and can be seen with quite small telescopes. The third comet is faint, but covers quite a large space. This comet was recently observed with a three-inch telescope and comet eye-piece. The comet was so faint that it could not be well defined or kept steadily in view. It was seen by flashes which were quite bright, and seemed to proceed from a center. If the last two comets have not already passed their perihelion, they may yet be seen with the naked eye.

Business Directory.

WM. BARTLING. HENRY KIMBALL.
BARTLING & KIMBALL,
BOOKBINDERS,
 Paper Rulers & Blank Book Manufacturers.
 505 Clay Street, (southwest corner Sansome),
 SAN FRANCISCO.

JOHN A. CHURCH, E. M. PH. D.
MINING ENGINEER,
 Room 75, 115 Broadway, New York.

Agent for PADDOCK'S Ore Dressing Machinery.
 Mining Machinery supplied.

San Francisco Cordage Company.

Established 1856.

We have just added a large amount of new machinery of the latest and most improved kind, and are again prepared to fill orders for Rope of any special lengths and sizes. Constantly on hand a large stock of Manila Rope, all sizes: Tarred Manila Rope; Hay Rope; Whale Line, etc., etc.
TUBBS & CO.,
 611 and 613 Front Street, San Francisco

DEWEY & CO'S
SCIENTIFIC PRESS
Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free. Address.

DEWEY & CO.,
 202 Sansome St., N. E. Cor. Pine,
 San Francisco.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 329 Sansome street, Room 10.

— PATENT —

LIFE-SAVING RESPIRATOR

Prevents Lead Poisoning and Salivation.

INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Mines, Guano Works, White Lead Corroding, Feeding Threshing Machines and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price \$3 each, or \$30 per dozen. Sent post-paid to any address upon receipt of price.

SETH MARSHALL, Jr., Agent,

309 California Street, San Francisco, Cal.

Send for Descriptive Circulars containing testimonials of well-known parties who are at present using them.

THE POOR MAN'S PROSPECTING
HAND OR POWER QUARTZ STAMP MILL.

The Stamp (41 inches) is greater than that of any of the heavy power Stamps. Stamps and Dies cast on Chill. These Machines are well and thoroughly made, nothing about them to get out of order. They are put together with bolts. Can be taken apart readily, so as to be convenient to pack on a mule's back. The whole machine weighs about 1,300 pounds. The heaviest piece weighs 200 lbs. These Mills will do more work (according to money invested) than any of the old heavy Stamp Mills. For sale at AMES' STEAM ENGINE DEPOT, 14 S. Canal street, Chicago, Illinois. Net Cash Price, \$150.

Two men can operate it all day. It is simple, efficient and durable. The force of the blow can be changed so as to strike a light or a very heavy blow readily. Two men can work this Mill to its full capacity, and do the work as well as can be done with any of the old-style heavy Stamp Mills. An inspection of this Machine will convince any practical person that it is the most perfect QUARTZ STAMP MILL ever produced in this or any other country. A large number of old practical Miners have seen it, and they all say it is a perfect Hand Stamp Mill. We put on a band pulley, so it can be run with power. The cut is a correct representation of C. EATON'S PATENT LATELY PERFECTED MILL.

— FOR —
PROSPECTING
 IT IS SIMPLY
Perfection!

When power is used each Stamp will strike 150 blows per minute. The force of the blow in comparison to the face of the Stamp cast on Chill. These Machines are well and thoroughly made, nothing about them to get out of order. They are put together with bolts. Can be taken apart readily, so as to be convenient to pack on a mule's back. The whole machine weighs about 1,300 pounds. The heaviest piece weighs 200 lbs. These Mills will do more work (according to money invested) than any of the old heavy Stamp Mills. For sale at AMES' STEAM ENGINE DEPOT, 14 S. Canal street, Chicago, Illinois. Net Cash Price, \$150.

THE ELKINS
"BOSS" GOLD AMALGAMATOR,

Is the Best, Simplest and Cheapest
Amalgamator in Use.

Nothing about it to get out of order or wear out. Weighs only 500 lbs.—heaviest piece weighs 160 lbs. Is automatic in its working. Measures, feeds, screens and passes all material through a large body of quicksilver; then washes and cleans without care or attention. Requires no more power than a large grindstone. Uses water over and over again where water is scarce. All water required can pass through a 2-inch pipe. Capacity, two to four tons per hour. Saves 90% of precious metals. Price, \$250. Pump \$25 extra. Send for circular.

ELKINS & LYNCH,

No. 318 Pine Street, - - SAN FRANCISCO.

Books for Miners and Millmen

KUSTEL'S ROASTING OF GOLD AND SILVER ORES, and the extraction of their respective metals without quicksilver. Illustrated. 142 pages. 1870. A valuable and carefully written work. Post-paid, \$2.50. Published and sold by Dewey & Co., S. F.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arseniurets, and gold and silver ores generally, with 120 lithographic diagrams. 1867. This work is unequalled by any other published embracing the subjects treated. Post-paid, \$7.50. Printed and sold by Dewey & Co., S. F.

PHILLIPS' EXPLORERS, MINERS AND METALLURGISTS COMPANION, comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy. 672 pages and 85 illustrations. A most valuable and comprehensive book of reference to prospectors and practical miners. Post-paid, \$10.50. Sold by Dewey & Co., S. F.

A-BON'S TESTING AND WORKING SILVER ORES. Illustrated. 111 pages. 1878. A useful and practical work, free from technicalities and extremely serviceable for miners' use. Post-paid, \$2. Published and sold by Dewey & Co., S. F.

COPP'S HANDBOOK OF MINING LAWS.—Containing the U. S. Mining Laws, Digest of Decisions, Forms, etc., 1877. Pocket size, and very handy and convenient for miners. Post-paid, \$1.00. Sold by Dewey & Co., S. F.

STEAM ENGINE.

For sale, a second hand engine in perfect order, mounted on good wagon. Suitable for a single mill or a portable saw mill, or for mining purposes. It is the LARGEST PORTABLE ENGINE IN THE STATE, too large for threshing. Will be sold very cheap, with reasonable time for payment if properly secured. Call and see it at

RICE'S ENGINE WORKS.

56 Bluxome Street, Near C. P. & S. P. R. R. Offices.

SPECIMENS.

CHOICE SPECIMENS of Quartz showing native Gold, Copper, Galena or Iron Sulphates, Pyrites or Clusters of Crystals, or Petrified Wood sent, postage paid, on receipt of \$1. Address **E. O. CRANE,** Bodie, Mono County, Cal.

F. MOORECROFT,
Stone Seal Engraver.

THURLOW BLOCK,

Room 38, 126 Kearny St., Cor. Sutter, San Francisco.

Coats of Arms, Crests, Monograms and Masonic Inscriptions Carefully Engraved

CAUTION—To Section Chimney Builders.

All chimneys on which joint bands with cement, or its equivalent, are used to make the joints smoke and fire-proof, with reds, clamps, or their substitutes, to brace the chimneys to the buildings, are INFRINGEMENTS on my patents. My patents for sectional chimneys have been sustained in every instance.

J. BROWELL, Pioneer Chimney Builder,
 412 Jackson St., S. F., and 1200 Broadway, Oakland

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

Metallurgy and Ores.

Nevada Metallurgical Works,

No. 23 STEVENSON STREET.
Near First and Market Streets.

Ores worked by any process.
Ores sampled.
ASSAYING in all its branches.
Analysis of Ores, Minerals, Waters, etc.
WORKING TESTS MADE.
Plans furnished for the most suitable process for working Ores.

Special attention paid to Examinations of Mines; plans and reports furnished.

E. HUNN,
C. A. LUCKHARDT,
Mining Engineers and Metallurgists

JOHN TAYLOR & CO.,

Importers of and Dealers in

ASSAYERS' MATERIALS,

CHEMICAL APPARATUS AND CHEMICALS, DRUGGISTS' GLASSWARE AND SUNORIES, Etc.

512 & 518 Washington St., San Francisco

We would call the special attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our stock of Clay Crucibles, Mullies, Dry Cups, etc., manufactured by the Patent Plumbago Crucible Co., of London, England, for which we have been made Sole Agents for the Pacific Coast. Circulars with prices will be sent upon application.

Also, to our large and well adapted stock of

Assayers' Materials & Chemical Apparatus,

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.
Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application.

JOHN TAYLOR & CO.

Channel Street, off foot of Fourth, San Francisco, Cal.

Highest price paid for Sulphurets, Arseniurets, Tellurides and Gold Ores generally.

METALLURGICAL WORKS,

STRONG & CO., 10 Stevenson Street, S. F.
ORES SAMPLED, TESTED, ASSAYED.

BROWN'S Ledger Papers.

Acknowledged to be the best Papers for Blank Books. Will resist the SEVEREST TEST of erasure and reworking. Received the HIGHEST AWARD over ALL OTHERS from the UNITED STATES CENTENNIAL COMMISSION. Have your Blank Books made from them, and no other.

H. S. CROCKER & CO., SOLE AGENTS.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

AN ENGINEER,

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is hoisted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

RUSSELL'S AMALGAMATOR.

Patented June 25th, 1878.

SAVE YOUR GOLD And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

BULLOCK & CRENSHAW, - 528 Arch St., Philadelphia,

Manufacturers and Importers of

Chemicals and Chemical Apparatus,

Suitable for Analytical, Technical and Experimental Use. Descriptive Priced Catalogues furnished on application

FRANCIS SMITH & CO.,

Manufacturers of

THE PATENT CHANNEL IRON WHEELBARROWS.

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipes on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

SHEET IRON PIPE.

Machinery.

GOLD AND SILVER Grinding and Amalgamating MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

SPERRY'S Wrought-Iron Frame FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc., Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,250.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

[CONTINUED FROM PAGE 181.]

low color and assays from \$200 to \$600.

ITEMS.—The Valley M. & M. Co. have recently made a good strike of rich ore at Hiko. The developments in the Day mine have greatly improved of late, and the indications are that they are sinking the winze on top of a large deposit of ore.

DISASTER PEAK DISTRICT.

ITEM.—Silver State, Sept. 11: Very favorable reports are received from the new mines recently discovered near Disaster Peak. A new district has been organized in the locality, and a lead discovered by Tom Shaw, is said to be one of the largest in the State. There is an immense body of ore on the surface, samples of which assay from \$115 to \$233 per ton. The district is situated about 40 miles a little west of north from Willow Creek station on the Idaho road.

ESMERALDA DISTRICT.

DEL MONTE.—Herald, Sept. 13: The erection of the gallow frame has been completed and the additional work on the building is being carried on as rapidly as possible. The station on the drain tunnel has been finished and strongly timbered. Several pieces of the new pumping machinery have arrived and are on the ground ready to be operated on so soon as the remainder arrives.

GOOD HOPE DISTRICT.

NEW STRIKE.—Silver State, Sept. 11: Charley Drew informs the *Times-Review* that a body of very rich black sulphure ore was struck in the Amazon mine, Good Hope district, last week. Shortly after the ore body was struck the men were driven out of the mine by a strong flow of water.

SAN ANTONIO DISTRICT.

ITEM.—Belmont Courier, Sept. 13: The Liberty, Potomac, Springfield, Twilight, Rigby, Vulcan, Las Animas, Aero-lite, Imperial, Ivy Green and Phoenix have been consolidated into one company. The pay chute of the Liberty mine is in the main fissure, but contains the rich ore from \$100 to \$500 per ton, in what is essentially a chimney. Outside of this the run is from \$20 to \$100 per ton. This mine is much broken up at the surface, the cropping to the northwest and west of the incline revealing a number of rich ledgers that have apparently been thrust up from below and then forced over and spread out toward the foot of the hill. The vein formation further up the mountain supports the theory, the ledge being well defined at the surface, and, as far as known, permanent in the dip. The fault along the line of which the movement has occurred has been carefully located, and a crosscut run below the break by Mr. Rigby just before the close of his management revealed the vein, lost some time previously on the upper level, where the break took place, between well defined walls, the vein matter consisting of quartz carrying ore of low grade. Potomac hill is the highest elevation in the district. Its formation is well adapted for tunneling. The main ledge is shown in prominent croppings extending across the summit and traversing the hills in a direction nearly north-west and south-east. To the southwest and along the slope of the hill there are strong indications of an outburst from below, as rich ore has been found at numerous points on the surface without any regularity of cropping or definiteness of dip. The tunnel that has been run into the hill from the southwest in a northeasterly direction is now in about 450 ft. and will soon strike the ledge at a depth of about 300 ft below the summit cropping.

WILLOW CREEK DISTRICT.

ITEMS.—Silver State, Sept. 12: Rich ore is now being taken out of the Ohio mine. Much of it assays from \$500 to \$1,000 per ton, and the new lead is said to be of the same quality as that of Salt Lake some time this month. The Moonlight mine is also looking well. The ledge is 14 ft wide and the ore assays from \$60 to \$125 per ton.

ARIZONA.

TOMBSTONE ITEMS.—From Citizen: The Tombstone mill averages one bar a day from Tough Nut ore. Grading for the Corbin mill is completed. Thoshaft on the Grand Central, eight by five ft in the clear, is down 45 ft in good ore. The Contention mill site is on the San Pedro, seven miles from the mouth of the Babacomari and 12 below the other mills. The Tough Nut employs 60 men. The main shaft is down 80 ft, and the new hoisting works are being put in place. The Arizona Transportation Co. (Hart Light's terms) haul the Tough Nut ore; last Monday one team hauled 20,000 and the other 30,000 pounds—the average is 13 tons per day. It is now held by the parties best qualified to judge, that the Contention and Tough Nut ledges are the same, which enhances the value of intervening claims.

ITEMS.—From Silver Belt: Capt. J. A. Powell has purchased a 10-stamp mill to be erected two miles south-west of the Buckeye mine. The main shaft on the Stone-wall has reached the depth of 290 ft. A level is being run at the bottom crosscutting the ledge. The Washington mine has been sold to an Eastern company. Hoisting works are to be erected and work prosecuted in earnest. The Chromo tunnel, belonging to Capt. J. A. Moore, has entered the ledge, and was in at last accounts, 34 ft, several feet higher, in fine ore. Cox & Corbin shaft is down 96 ft in good ore from top to bottom, some of which worked last week in Isabella mill, \$312 per ton. Selected ore went much higher, some of it yielding dollars per pound. The Pilgrim has a vein three ft wide, some of it assays \$3 per pound. The strike in the Southwest Alice, this week, is indicative of a big mine. A crosscut to the northwest at the depth of 100 ft has revealed a large body of chert ore, in fine ore. Over 300 feet in seven feet the footwall has not yet been reached. Isabella mill is now getting away with six to eight tons of ore daily, and every prospect for keeping up this desirable state of things indefinitely.

RICHMOND BASIN.—The Bilderbacks and Steve O'Neill are working the South La Plata and are getting ore which assays upward of \$500. The La Plata shows well. It is sunk upon 30 ft below water level. The Nugget company are timbering their main shaft, which is down 100 ft. When that is done they will crosscut the ledge and also sink another 100 feet and again cut the ledge. The same company have also another shaft down 60 ft on a spur which runs from the Mack Morris side ground, and about 60 ft from the Mack Morris south line. It also shows good ore, silver glance, and will assay at least \$1,000. The pay streak is two ft wide.

ITEMS.—From Arizona: Charley Reyes, from Groom creek, reported last night. He has been endeavoring to free his shaft from water, but thinks he is getting the worst of it, and the fluid holds possession of four feet in the bottom of the shaft. At 50 ft he is taking out rich gold ore.

RICH STRIKE.—The Star is authority for the report that a rich find has been made on the east side of Huachuca and about eight miles from the center. Over 300 ledgers have been made, which includes all of the valuable property. The ledges are very wide and a number of assays which have been made average \$480 to the ton in silver. Although the discovery was only made a few days ago, there are over 100 men on the ground. There is considerable excitement in the district.

HASHLAW.—Work on the tunnel is now under headway. Twenty ft has already been opened. There are two workings, one on each side of the mountain. The size of tunnels is 10x14 ft. Three shifts of men are at work night and day. The road from the mine to the mill site has been surveyed and is being graded; when finished the grade will be two and one-half inches to 100 ft. While there is plenty of surface water for all milling purposes, the company propose to run a ditch up the gulch in such a way as to draw in all the water from the gulch and slop. This will give them a supply which will be sufficient to meet any emergency, even a drouth.

COLORADO.

GILPIN COUNTY.—Register-Cat, Sept. 12: The Harkaway lode on Negro hill, near Central City, consists of 1,500 ft of contiguous property. It has been developed through a series of shafts ranging from 10 to 100 feet deep, and several levels from the main to the air shafts, east

and west. A whim is being erected over the main shaft. A level is now being driven from the No. 1 shaft east to a depth of 60 ft to connect with the main shaft. The output of pay material from this level is three tons per day, product of two miners' labor. The material prospects well enough in free gold by the simple process of panning, to yield under stamps 9 ounces gold per cord.

SILVER CLOUD LODE.—Georgetown Courier, Sept. 11: Located east of Terrible lode, on Sherman mountain. The upper level of the east part of the lode is a vein of galena and blende six inches thick. Last mill run returned 450 oz., second class. Stopping west of main shaft in several small veins of ore averaging three inches solid with gray copper, valued at 200 oz.

LITTLE QUEEN LODE.—One-half mile west of Kokomo lode. Eighty feet wide and runs directly over the mountain. Adit at base of mountain is in 63 feet and shows a continuous ore vein the whole length with the exception of the first eight feet, the vein being in places 46 inches thick, and will average fully three feet. The ore is mostly decomposed and carries the carbonates of copper and some gray copper. There are also bunches of galena in it. None of the ore has yet been sold, there being about 30 tons on hand which is estimated to be worth \$200 per ton in gold and silver. Assays as high as 13.12 oz. in gold and 239 oz. in silver have been obtained. About two-thirds of the ore vein is good milling ore, the remainder being chiefly quartz. The ground is soft, and with the exception of an occasional feldspar bar it can be worked without using powder. In drifting they are able to take out about two tons of ore per day.

WHITE MINE.—In the Cleary adit the breast shows ore scattered through the whole crevice and about three-fourths of the ground broken contains pay. The stope directly back of the breast is about 200 ft long, and for the first 50 feet shows a number of ore veins ranging from six inches in thickness downwards, the whole of which will aggregate about a foot of solid, besides a large amount of concentrating ore. At other places nearly the whole of the stope is a milling ore that will average 100 oz. per ton. This adit, when driven, showed but small quantities of ore for the most of the distance, but as the stope has been raised the quantity has continually increased until now it is very large. Two stopes have lately been started nearer the mouth and both are producing. The ore from this place mills from 100 to 300 oz., according to class.

CLIFFORD LODE.—This lode is near the top of the divide between Fall river and Nevada. Main shaft is down 165 feet, where a new level has been started. The ore vein ranges from 6 to 18 inches in thickness, and at the last sale gave a return of 535 oz., first class; 220 oz. second class, and 135 oz. third class. The company are sinking the discovery shaft, which has now reached a depth of 60 feet and shows a vein of ore from two to three inches thick, similar in character to that from the main shaft.

IDAHO.

ITEMS.—The Statesman says: The Rising Sun M. Co. has opened a head of their amethyst running on first class ore from the mine. The mine has been opened to a depth of 40 feet from the surface and for a considerable distance along the vein, and with these developments is showing a splendid body of ore. The long spell of excessively dry weather has reduced the water in Robie's gulch so that it is only practicable to run the amethyst a few hours in the day. Al. Hoskins came down from his mine on Shaw's mountain and brought a piece of rock that glistened all over with gold. He has been mining for some time, 10 ft long and 8 ft wide. At Snake river the yield of bullion is quite large. Howes and Pitts ship about \$1,000 per month. N. R. Woodworth is doing equally as well with small machines of 25 ft of plates per machine. Several machines are running with a capacity of 200 square feet. The World says: Ten tons of ore from the Golconda mine, situated at the head of More creek, arrived at Plowman's mill last Sunday.

Solving Metallurgical Difficulties.

EDITORS PRESS:—Although the milling of gold ores has been practiced in this country for more than thirty years, and has been conducted on the greatest scale, the theory of the process remains in doubt to this day.

In Austria, where a bath of quicksilver one-half to one inch thick was used to collect the gold, the tendency of opinion was to consider amalgamation as a mechanical act—the gold collected in the mercury simply because it was heavy enough to sink in it and thus remove itself from the rush of the pulp through the amalgamator. But the introduction of copper plates covered with a mere coating of amalgam, which has been the constant practice in American mills, has revived the theory that amalgamation is a chemical instead of a mechanical act.

This question is one of great practical importance. It is perfectly true that a mill furnished with a given set of amalgamating machines will do just as good work on one theory as on the other, but a proper understanding of this question must be arrived at before it can be possible to decide whether the machinery used is the best that can be had.

An impression is very common among miners that milling as now practiced does not give good results, and that better work could be done in a great many mills if we only knew how. This knowledge will never be arrived at until the mills subject themselves to close criticism, by ascertaining carefully the value of the ore by fire assay and comparing it with the mill returns.

This subject is one that I have already given attention to, but the facts in my possession are too limited to form a sound basis for conclusions. They also labor under the disadvantage of being derived from Colorado more than from California, and it is not necessary to tell your readers that the ores of the two districts are not the same.

I am anxious to obtain as large a number of assays of California gold ores as possible, and I appeal to the large body of practical men who read the PRESS to send me what they have, however few and however many.

My particular object is to ascertain how much silver there is in combination with the gold, as exhibited by the fire assay, and I shall be thankful for assays whether they represent ores that have been milled or not. When the ores have been milled I would like to know the number of tons, and if possible the yield in the mill, both of gold and silver. My intention is to accumulate a large number of assays in order to obtain average results that will be trustworthy. Assays of hydraulic gold and hydraulic gravels will be particularly useful, though the purpose

of my inquiry is to ascertain the true character of the gold in the vein quartz.

I have no intention of probing business secrets, and in publishing only averages will be used, so that no criticism will be made on special mills. When a sufficient number of assays have been received, I intend to communicate the results and my conclusions upon them to the public.

To repeat, the items I desire to have are:

1. The amount of gold and silver in this ore by assay.
2. The return by the mill process.
3. The number of tons treated.
4. The name of the assayer.

For any information on this subject the sender will receive the thanks of yours very truly,

JOHN A. CHURCH, M. E.
115 Broadway, N. Y., Sept. 6th, 1879.

News in Brief.

The insurrection in Cuba continues.

REPORTS from the Cassiar mines are still discouraging.

ENCOURAGING news is received from the mines in Alaska.

The gold fever in Queens county, Nova Scotia, shows no abatement.

THE Banco del Comercio, of Havana, has suspended payment.

It is reported that Suleiman Pasha died at Bagdad last Saturday.

THE Olcolical Institute of the Kiel University has been destroyed by fire.

ENGLAND will have to import 16,000,000 quarters of wheat this year.

THE cotton operatives on strikes at Ashton, Eng., number 8,000 to 10,000.

SANTA BARBARA narrowly escaped being destroyed by fire last Saturday.

WM. H. HOLMES, a pioneer, died at Oregon City, Or., last Saturday, aged 70 years.

EVERYTHING is quiet at Sitka, and the civil government is working smoothly.

THERE is a great scarcity of food in Kashgar and people are suffering severely.

Low water has caused a suspension of navigation on Snake river in Oregon.

THE Washington county fair will open at Hillsboro, Or., on the 22d inst.

GREAT distress among the working classes in England is apprehended this winter.

THE British Residency has left Mandalay, fearing a repetition of the Cabul massacre.

SILVER in London, 51½d; consols, 97 11-16; 5% U. S. bonds, 105½; 4s, 105½; 4½s, 108½.

HOR picking on Puget sound is now fully under way, being mostly done by Indians.

GOLD to the amount of 23,000,000 francs will leave France for the United States this week.

FIVE new cases of yellow fever are reported at Morgan City, La., and two at New Orleans.

THE opening of the Industrial fair at Portland, Or., has been postponed until October 20th.

THE Austrians have begun the occupation of Novi Bazar, and have met with friendly receptions.

In the second ballot at Bordeaux for member of the Chamber of Deputies Blanqui was defeated.

AT Liverpool wheat is quoted at 8s 9d@9s 7d for average California white, and 9s 7d@10s for club.

A MINER was found dead in the Savage incline at Virginia Sept. 16th, his flesh being fairly cooked.

ORDERS have been issued to the British troops to occupy Cabul with or without the Ameer's consent.

A TERRIBLE storm on the coast of Bolivia recently destroyed a great deal of property and some lives.

HANLAN and Courtney are to row on Chautauque lake, N. Y., October 8th, for a purse of \$6,000.

THE rural population of Roumania is suffering from famine caused by the failure of the maize crop.

It is proposed in Cuba to import 25,000 to 30,000 Chinamen yearly until the number reaches 400,000.

No further steps are to be taken in the negotiations between Germany and the Vatican until the Prussian elections are over.

THE workings of the Stanton colliery, at Mahanoy Plane, Pa., are caving in, compelling the occupants of houses to vacate them.

IN San Francisco half dollars are quoted at 99½ buying, 99½ selling; trade dollars, 97 buying, 98 selling; Mexican dollars, 91 buying, 92 selling.

IN New York Government bonds were quoted at 101½ for 4s of 1907; 102½ for 5s of 1881; 104½ for 4½s; sterling, \$4.82@4.84; silver bars, 111½; silver coin, ½@1 discount.

THE Maryland Republican State Convention met at Baltimore Sept. 16th and nominated a full ticket, with James A. Cray, of Howard county, for Governor.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Northern Belle, Sept. 10th, \$2,736 82; Martin White, Sept. 10th, \$4,500 55; Hillside, Sept. 13th, \$5,000; Independence, Sept. 12th, \$3,500; Belle Isle, Sept. 15th, \$25,100; Grand Prize, Sept. 15th, \$4,800; Northern Belle, Sept. 13th, \$4,538 08; Martin White, Sept. 14th, \$4,700; Hillside, Sept. 18th, \$4,700.

PATENTS AND INVENTIONS.**List of U. S. Patents Issued to Pacific Coast Inventors.**

[FROM OFFICIAL REPORTS TO DEWEY & CO.'S MINING AND SCIENTIFIC PRESS PATENT AGENCY.]

FOR THE WEEK ENDING SEPTEMBER 9TH, 1879.

219,467.—GANG PLOW.—Reuben Hart and M. P. Nicholson, Santa Maria, Cal.
219,512.—CAR TRUCK.—W. E. Payton, Stockton, Cal.
219,521.—MIXER BOX.—J. Reid, Portland, Ore.
219,520.—PORTABLE ENGINE BOILER.—H. W. Rice, S. F.
219,530.—FIRR-PLACE.—F. A. Sage, St. Helena, Cal.
7,664.—CIGARS.—Trademark.—Sanderson & Horn, S. F.
2,000.—TITLE "SYRUP OF FIGS"—Label.—W. Pinnington and R. E. Queen, Reno, Nev.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

GANG PLOW.—Reuben Hart and Milford P. Nicholson, Santa Maria, Cal. Dated Sept. 9th, 1879. No. 219,467. This invention consists in a novel method of mounting the plows upon a frame, and in a means for supporting the frames and plows upon the bearing-wheels, so that they may be raised to entirely clear the ground, or lowered to make any depth of cut desired. The rear and front plows are capable of an independent motion, by means of separate levers, so that either front or rear plows may be elevated or depressed independent of each other. This construction has many advantages over the ordinary sulky or gang plows.

FIRR-PLACE.—Francis A. Sage, St. Helena, Cal. Dated Sept. 9th, 1879. No. 219,530. This invention consists in providing a supplemental flue, built beside the main flue, the supplemental flue being connected with the back or arch of the fire-place by a series of openings or slots, which may be closed by dampers. An increased draft for any part of the fire may be maintained by removing the dampers from any of the openings, so that the products of combustion may pass directly to the supplemental flue in case there is not a proper draft through the main flue. On removing or sliding any one of the dampers so as to uncover any one of the openings or slots, a current of air is immediately carried through the fire opposite the location of the opening, and the draft thereby induced assists combustion at that point.

CAR-TRUCKS.—Wm. E. Peyton, Stockton, Cal. Dated Sept. 9th, 1879. No. 219,512. This invention relates to improvements in that class of railway car-trucks in which the two axles of a truck are, to a certain degree, independent of each other, so that in rounding a curve there is no drag or friction of the wheels on the rails. The improvements consist in certain details of construction whereby very little change in existing conditions is made, while at the same time the front and rear axles are sufficiently independent of each other, so that there is no friction on the rails in rounding curves.

PORTABLE ENGINE BOILER.—H. W. Rice, 56 Bluxome street, San Francisco. Dated Sept. 9th, 1879. No. 219,523. This invention relates to certain improvements in portable engine boilers of that class known as "return-flue" boilers, in which a large flue near the bottom serves at once as a furnace and to convey the products of combustion to a rear combustion chamber, from which they are returned through small tubes above and at the sides of the main flue to the chimney and uptake at the front.

MAINE MINES.—The mines of Sullivan, Me., alluded to in a former issue, seem to be developing to a certain extent. We learn from the New York Mail that the Sullivan vein shows large amounts of highly encouraging sulphides, with a small amount of telluride ore. At Gouldsboro' the vein is well defined ore, galena and copper sulphides. About 300 tons of ore of all grades have been taken out. The ore is claimed to assay from 25 to 350 ounces per ton, but rock carrying five ounces per ton can be profitably worked. Stock of the mines of a par value of \$10 is generally quoted at \$1.50. The alleged richness and quantity of ore in these mines ought to send the Maine mining stocks just a little higher.

Quicksilver Mining Publication.

Memoir on the Mines and Works of Almaden, by M. H. Kues, M. E. Translated from the "Annales des Mines" for the MINING AND SCIENTIFIC PRESS, by S. B. CHRISTY. CONTENTS.—PART I.—Geological Description of the Deposits at Almaden: 1. Introduction; 2. Geological Situation and Constitution; 3. Strata; 4. Devonian System; 5. Eruptive Rocks; 6. Deposits of Mercury; Description of the Mine; Mineralogical Constitution of the Vein Matter; Age of the Veins; Abandoned Mines. PART II.—Exploitation of the Mines of Almaden: 1. Method of Exploitation; 2. Organization of Labor; 3. Mechanical Preparation. PART III.—Metallurgy of Mercury at Almaden: 1. Description of the Works; 2. Treatment of the Ore; 3. Losses of Treatment. PART IV.—Administration and History: 2. History: 48 large pamphlet pages, post-paid, 50 cents. DEWEY & CO., Publishers, S. F., 1879.

Lathe Without Saw Attachments.

Material eighteen inches long and eight inches in diameter can be turned upon it. The pieces that accompany this lathe without extra charge are two 1" rears, two plain centers, one spur center for wood turning, and one face plate.

This lathe has been made especially to meet a want felt by many for a really good and substantially made Foot-Lathe at a reasonable price, and we think that we can safely say that it is by far the best Lathe ever placed on the market at the price asked. The bed, head, and tail stocks are of iron; the spindles of steel. The bearing of the head stock is conical, so that the wear can be easily taken up.

Price of Lathe without Saw Attachments.....\$45. Price of Lathe with SCROLL Saw Attachment.....\$55.
Price of Lathe with both Scroll and Circular Saws, \$70.

Trump Drill Chuck.

Chuck for drills $\frac{1}{8}$ and under, Price.....\$1.50
Chuck, for drills $\frac{1}{4}$ and under, Price.....\$2.25
They are made on solid steel plug, centered and readily fitted to Lathe or Drill Press.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

GIANT POWDER

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS
Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

Colorado River Canyons.

We give an illustration on this page of the Mu-av canyon, a side gorge of the Grand canyon of the Colorado. It is impossible for a mere description to convey any but a faint idea of the sublimity that lines the banks of the Colorado of the West. The walls rise in many instances more than a mile in height, a thousand feet of which is up through granite crags, then steep slopes and perpendicular cliffs rise one above another to the summit. The gorge is black and narrow below, red and gray and flaring above, with crags and angular projections on the walls, which, cut in many places by side canyons, seem to be a vast wilderness of rocks. The waters of the river rush their winding way through the gloomy depths, plunging over steep declivities with a mad roar, spreading out into a placid bosom in some opening beyond. Clouds play in the canyon, or roll down in great masses filling the gorge with gloom, sometimes hanging above from wall to wall, covering the canyon with a roof of impending storm.

Ever and anon a gust of wind sweeps down a side gulch, making a rift in the clouds, and revealing the blue heavens. In some localities volcanic evidences accumulate. Great quantities of cooled lava, and many cinder cones are seen on either side, and then comes an abrupt cataract. Just over the fall a well-defined crater stands on the very brink of the canyon. From this volcano vast floods of lava have doubtless been poured over the canyon wall, where the cataract now rushes. The whole north side, as far as the eye can reach, is lined with the black basalt, and high up on the opposite wall are patches of the same material resting on the benches, filling old alcoves and caves. Directly under the volcanic cone the rocks are broken in two along a line which crosses the river, and the beds have dropped 800 feet on the lower side of this line forming a fault.

Prof. J. W. Powell, in his report on the Colorado of the West, in referring to the volcanic features in one of the canyons, says: "We have no difficulty as we float along, and I am able to observe the wonderful phenomena connected with this flood of lava. The canyon was doubtless filled to a height of 1,200 or 1,500 feet, perhaps by more than one flood. This would dam the water back; and in cutting through this great lava bed, a new channel has been formed, sometimes on one side, sometimes on the other. The cooled lava, being of firmer texture than the rocks of which the walls are composed, remains in some places; in others a narrow channel has been cut, leaving a line of basalt on either side. It is possible that the lava cooled faster on the sides against the walls, and that the center ran out; but of this we can only conjecture. There are other places, where almost the whole of the lava is gone, patches of it only being seen where it has caught on the walls. As we float down, we can see that it ran out into side canyons. In some places this basalt has a fine, columnar structure, often in concentric prisms, and masses of these concentric columns have coalesced. In some places, when the flow occurred, the canyon was probably at about the same depth as it is now, for we can see where the basalt has rolled out on the sands, and, what seems curious to me, the sands are not melted or metamorphosed to any appreciable extent. In places the bed of the river is of sandstone or limestone, in other places of lava, showing that it has all been cut out again where the sandstones and limestones appear; but there is a little yet left where the bed is of lava.

"What a conflict of water and fire there must have been here! Just imagine a river of molten rock, running down into a river of melted snow. What a seething and boiling of the waters; what clouds of steam rolled into the heavens!"

A NEW MINING REVIEW.—The first number of the *Colorado Mining Review*, published by Warder Cumming, at Denver, Colorado, comes to us with its volume full of information concerning the mining interests of that State. It has a pleasant, cheerful appearance, and we wish success to the new enterprise in its important and growing field of observation.

Division of Electric Light.

At the late meeting at Saratoga of the American Association for the Advancement of Science, Mr. Edison, in his address, alluded to the results attained by him in solving the question of the practical divisibility of the electric light. As reported in No. 194 of the *Scientific American Supplement*, page 3,089, he says: "I am enabled by the increased capacity of platinum to withstand high temperature, to employ small radiating surfaces, and thus reduce the energy required per candle light. I can now obtain eight separate jets, each giving out an absolutely steady light and equal to 16 standard candles, or a total of 128 candles, by the expen-

silk, arranged upon cards and placed side by side, could be distinguished as readily as by sunlight. Had it not been for the loss of light, occasioned by the size of the reflecting mirrors, we believe the light could have been subdivided to its fullest extent and into at least 50 separate lights. The whole light from the main lamp can be divided and subdivided, and distributed down to a single ray even, at pleasure. The dispersing lenses and reflectors are arranged inside the building so as to illuminate every part, without any obscure corners. In the open air, the rays of light thrown upon objects over a mile away, in the darkness of night, brought them into view with startling distinctness.

CONSOLIDATION OF CALIFORNIA HYDRAULICS. The last issue of the *Bullion* has the following editorial paragraph which contains its

Determining Slag Densities in Smelting.

Prof. Abich was the first to point out the relation existing between the composition of volcanic rocks and their densities, and to show that, the latter being ascertained, very correct conclusions might be drawn as to their content of silica. The general rule is that the most silicious rocks are the lightest, and the most basic have the highest specific gravity. Thomas Macfarlane, in a paper read at the Pittsburg meeting of the American Institute of Mining Engineers, says that from this general rule it occurred to him that by determining the density of slags it might be possible to judge more accurately of their nature than by observing merely their superficial appearances. In smelting copper, lead and silver ores, it is scarcely possible in every case to make analysis of the various parcels of ore, with the view of combining these and the fluxes, so accurately as to yield, in the furnace, slags of exactly the most favorable composition. This is even more difficult with ores which require previous calcination, or with matters which have been roasted in heaps. Even in cases where the greatest pains have been taken and the most elaborate calculations made beforehand, it frequently happens that variations in the working of the furnace interfere with the result so much desired. Generally, the practical metallurgist must be content with ascertaining the average composition of his ores and fluxes, making a calculation, once for all, as to the most advantageous mixture, and leaving slight changes in its composition to be taken care of as it is passing through the furnace. The various products then afford him the best material whereon to base his judgment as to the manner in which his smelting mixture and furnace are working. Of course, the character of the slag is one of his chief guides, but it is not always possible, from its outward characters alone, to form a correct judgment as to its composition. Neither would it be possible or practicable to apply chemical analysis for this purpose, as it would be impossible to wait for its results while working a furnace. Hence, Prof. Macfarlane proposes to determine the density of slags, so as to judge of the manner in which a furnace and its contents are working.

From numerous experiments made in silver, copper, lead and iron ores, it was ascertained that there was a gradual increase of density as the silica decreased, but the rule was not absolute, and only applicable where the relative quantity of the different bases in a slag remains the same. In smelting ferruginous ores, and lead and copper matters, the quantity of protoxide of iron in the slag, in proportion to the other bases, is usually greater, and this increases its density, although the percentage of silica may remain the same. An examination of a slag from smelting lead matte showed an increase of 7.53% in the ferric oxide, causing considerable increase in density, while the silica remained nearly the same.

The general rule, however, holds good, that the density in slags increases as their percentages of silica decrease. To illustrate—the smelting furnaces is furnished with a tapping-hole at the bottom, besides the usual "lead well" and slag spout. The tapping occasions no difficulty, and so long as the slag is not allowed to become too heavy, no incrustations are deposited in the furnace. The charging is managed in the following way: The smelting mixture is made up of ore and fluxes, and is calculated to yield a slag containing 32% of silica. The slag necessary to keep the charge open is added separately, in the proportion of about one-third of the smelting mixture. When the furnace yields a slag of greater density than 3.8, the proportion of added slag is decreased. The latter is, on the other hand, increased when the slag produced is lighter than 3.6. By ascertaining the specific gravity of the slag frequently, and altering the charge in the manner described, the furnaces are found to work regularly and satisfactorily. Of course, attention to the composition of slags alone will not enable the smelting to be done in the best possible manner. The metallurgist has many points to consider at one and the same time while conducting smelting operations. Ascertaining approximately the amount of silica in slags, with comparative ease and accuracy, is only one of these points.

MU-AV CANYON.

diture of 30,000 foot pounds of energy, or less than one horse power." We are not prepared to say whether this is or is not a wonderful achievement. Without making any comparisons and leaving all to draw their own conclusions, we give the result of experiments of which we were an eye witness at the atelier of Messrs. Molera & Cebrian in this city. The light used by them was a 4,000-candle electric light, enclosed in a chamber, on one side of which was a 24-inch Fresnel lens, from which the light is projected in parallel lines. The whole or any number of these lines or rays of light may be collected on a mirror or reflecting surface of any kind, and distributed in any greater or less intensity through secondary lenses without additional loss. In the experiment hardly one-half of the main light was collected, but it was divided into 16 separate lights, equal to 80 candles each. The secondary lenses were of small size, and situated in the ceiling, the light being thrown down. The quality of the light was equal to pure diffused daylight—in fact, several hundred shades of

own information: We are advised of the probable consolidation, under the auspices of a New York promoting company, of several of the most important hydraulic and drift or gravel mines in California. The proposed consolidation will, if effected, constitute by odds the largest gold property in the world, and one of the best equipped. The originators of the enterprise have been quietly bonding properties so connected that the same water can be used two or three times, and that other facilities, such as tunnels, drifts and flumes, can be used more fully. The project is to virtually place one entire grand mining district, that has some hundreds of managers, most of them mutually antagonistic, under one management. This seems to us by far the most important mining enterprise broached this season. As the bonds have been taken very low, in all probability, and the new management will be able to doubly use facilities, it is likely to prove immensely profitable to the managers, but at the same time the product of gold from this already important district will be largely increased.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Ers.

Valuable Salt Works.

EDITORS PRESS:—Twelve miles southeast of New Boston and eight northeast of Belleville, in the center of one of the large, even valleys of Nevada, is a salt lake or marsh of remarkable features, and one of probably great economic value in the future of the country. During the winter it is a shallow lake, but in the summer dries to a level with the earthy surface. Its size is about a mile and a half in width and three miles in length. It is called Rhodes Marsh, after the active man who has taken the principal part in its development, as well as of a number of other important enterprises in the region. Probably no purer salt can be found in any part of the world than is found here. Facilities for its manufacture are very peculiar.

The marsh is underlain everywhere at the depth of four or five feet by a hardpan of solid salt, up through which, by thousands of small holes—some few large, five or six inches in diameter—rises, during the summer evaporation, the clearest of waters, charged to its utmost capacity with salt in solution. Now, by simply digging pits, like tanners' vats, into the hardpan, and clearing all off smooth, the workmen see the pure brine flowing in of itself to fill the pit nearly full. Evaporation then begins and the salt soon commences to crystallize and fall to the bottom, in form like the cleanest, whitest sand possible. This process goes on continually on for weeks, till the pits may be filled two or three feet deep with the very purest salt known, when men dressed in gum garments go into the pits and shovel out the accumulated deposits for market all fit for use. Yet, if a finer article for the table is needed, a simple salt-mill near the works reduces the material to the best pulverized salt in the world.

We were greatly interested in all we saw when riding with the superintendent, Mr. Wasam, over this marsh, along its winding roads among the many pits; for solid wagon-roads are everywhere easily made by slightly throwing up the quickly drying, salt-hardened earth. The vats appeared of the richest, light yellow color, as the pure salt was seen at the bottom through the clear briny liquid, while the heaps and ridges shoveled out upon the banks were white as snow.

At the Philadelphia Centennial, this salt, taken directly from the vats as nature alone had deposited it, with no artificial improvement whatever, received the first premium as the best in the exhibition. Thousands and millions of tons can here be gathered, and exported to meet the wants of the whole coast. As soon as the Reese River railroad, from Battle Mountain, shall be completed through to near this place, an immense quantity of this best of salt must be yearly gathered and exported for use.

But besides the salt in this marsh, there are also in some parts large deposits of borax, from which hundreds of tons of the best quality have been manufactured. But the expense of freighting the teams long distances has rendered it difficult to compete at present with other places of its production nearer market. Yet with a railroad, all such difficulty will be removed and the borax of this marsh become an important article of trade.

Another fact of great interest is that at a short distance around this marsh the dry, rich, sage-brush surface of the valley has below it, at the depth of only 8, 12 or 15 feet, an abundance of good fresh water, so that by means of simple, home-made windmills, fine farms, from 10 to 50 acres, could easily be cultivated by irrigation in highest perfection, whenever such cultivation shall be needed. Should a salt-lake city here ever spring up, it could easily thus secure its supplies of fresh home provisions.

We must also include in this article a short account of the one mining locality of well-developed claims in this region; for while there are numerous fine-appearing leads in this vicinity, yet, mainly for the want of water, Belleville, with its mining camp, Candelaria, is the only point where for years vigorous and successful work in mining has been carried on. This town is to the southwest eight miles, over a slight elevation, and in the mountain range, located at this place, because here, from a distance of 12 miles, water, through iron pipes, could be brought in sufficient quantity to supply the necessities of the crushing mills and village of laborers. Here, therefore, good water can be had, yet its regular price is 2 cents a gallon, or about 10 cents the pail.

Belleville is a moderately pleasant village, of perhaps 600 people, all in lightly-constructed buildings, for temporary residence, as if hoping to make sufficient money to migrate to greener parts. Not a street can be sprinkled, nor yard irrigated, nor ornamental tree cultivated, for there is no water for these purposes. Residences for the principal managers of the mills—two or three rather pleasant frame buildings—have been put up, but these are the only painted buildings in the place. There is no mining done here, only the reduction of ore in the two large 40-stamp mills, one only of which is kept

constantly running. This ore is hauled by teams seven miles, from the mining locality southeast, called Candelaria. At this point water is only had by hauling another seven miles, from Columbus, farther to the southeast, and is sold for 5 cents per gallon, or 25 cents a pail. Still, a thriving, busy town has sprung up, very near the same size as Belleville. Black, irregular, basaltic hills rise around it, rugged and romantic; but its rich mines lie just to the south, in a grand precipitous rocky range, rising from the very edge of the little village, near a thousand feet in height, so steep as to be difficult or even dangerous to crawl up. The principal claim is that of the Northern Belle, finely developed and paying regularly large dividends, as all specially interested in mining stocks already know. The company owning this claim has secured, also, other valuable ones, and own the mills at Belleville. The Victor is a fine separate claim, in which the controlling interest is possessed by Mr. Rhodes, of the salt marsh and of New Boston. The ore is hauled from this mine nearly 20 miles west, to Marietta, for crushing. The hauling is done mostly by Mr. Rhodes' own teams, for which he has over 100 excellent mules and horses, providing for them convenient yards, stable and needed shops complete, the best arranged and best managed we have seen in the State. We did not go into this claim, but the reports of all were in agreement as to its great value.

Just over the range, the Mt. Diablo was well spoken of as having in the past paid largely, but, for some reason, at present little work is there being done. The want of water in the region, for milling purposes, is the great embarrassment, for which there seems to be no remedy at present known. The mill at Marietta, 14 miles west of Belleville, is supplied with water by wells, and here in the valley there is enough for any number of other mills. But the expense of hauling the ore this distance is necessarily great. Possibly a narrow-gauge railroad could, in an important manner, remedy this.

From Marietta west another vacancy in mining occurs, of about 50 miles, to Aurora, though by a line, through lofty, desolate, irregular mountains, the distance might be less than 40. This town is an old, well known mining locality, too well known to require an extended account. Ten or fifteen millions of dollars, it is said, have been taken, mostly from near the surface, at this place, but the leads, on being worked downwards, were of a nature to discourage the owners, hence mining, to a large extent, was given up. But of late, one prominent claim, the Real Del Monte has been taken hold of in earnest, by those interested, and a shaft is being put down, with a pumping apparatus and hoisting works, the most powerful in the State, the company being determined to test the claim thoroughly and know what there is below. Till this is done all other mining claimants seem to suspend operations, watching the Del Norte developments, hoping for the best and doing nothing till they know. But, from all which we could see and learn of the condition of things in this once famous locality, we do expect that Aurora will experience a revival of mining activity more extensive and more remunerative than ever it has yet known.

S. V. B.

Poisoned Water.

EDITORS PRESS:—In your issue of September 13th Mr. E. W. Hilgard makes many plain statements which I believe to be true. I have resided in California eighteen months, and have been surprised at the quantity of "galvanized" pipe used for water. Some eight years ago the matter was fully discussed in Boston and New England papers, and the pipe condemned as unfit for use. The Boston *Journal of Chemistry*, after full investigation, warned the people against its use for conveyance of water, and my impression is that but small quantity of such pipe is now used in the Eastern States.

I think all waters act upon zinc, and in no case is it safe to drink water after it has passed through "galvanized" pipe. I have known of one death, and many cases of sickness where the cause was traced directly to the use of water through "galvanized" pipe.

While visiting the Deaf and Dumb Institution at Berkeley I called attention to the large amount of "galvanized" pipe in use for conveyance of water in that institution. I sent to Boston for papers giving the analysis of water through "galvanized" pipe; also, the action of a town near Boston in regard to "galvanized" pipe. I am told the matter was submitted to the State assayer for investigation.

Some of the symptoms of zinc poison: Pains over and about the eyes, soreness in the pit of stomach, weakness of knees, numbness of hands and feet.

Volcano, Amador Co.

MONTANA, during the past 16 years, has produced \$153,000,000 worth of gold and silver. Of this sum \$147,000,000 was in gold. There are already 20,000 quartz claims in the Territory. Iron and lead mines have been opened, and coal is plentiful.

INCREASED activity in gold mining is reported from Nova Scotia. The total yield of gold in Nova Scotia from its discovery to the first of the present year has been 233,570 ounces, 16 dwt. and 15 grains, and the quartz crushed 376,212 tons.

Alaska and Its People.

In a relation of personal observations on Alaska by Archbishop Seghers and his party, the Yukon river is described as a magnificent stream. Taking the Amazon as the first and the Mississippi as the second of American rivers, the Yukon is the third in size. At the point where the Bishop's party reached it, some hundreds of miles from its mouth, the Yukon is three miles in width, and studded with islands as far as the eye can reach. An idea of its volume of water can be gathered from the fact that out in the open sea, six miles from the mouth of the river, the water taken from its stream is still fresh enough to drink. The length of the Yukon is over 3,000 miles, and it is navigable for steamers of considerable size for over 2,500 miles of its course. Further up, where the Yukon receives a large tributary, the Porcupine, the basin formed at the confluence of the two rivers, is 24 miles in width.

The Yukon was reached after a four-days' march due east from Norton's sound, across a country which is one continuous marsh, save only the low hills now and then encountered. Mosquitoes "literally blackened the sky." Grouse were found in abundance, and it was chiefly upon their flesh that the party subsisted.

Navigation on the Yukon is carried on by means of a *bidara*, a sailing vessel consisting of a light frame-work of wood, covered by skins of the hair seal.

The party arrived at Nulato about the end of July. The language is a corruption of some Russian dialect, and consists of only a few hundred words. It is so simple, so undeveloped that the same word, accompanied though by a different gesture of the hand in each instance, is made to do service for the past, present and future tenses of the verb.

The first ice made its appearance in the beginning of September. On the 10th of October the river froze over, or rather hocked up, great cakes and fields of ice drifting down stream with the rapid current, forming a gorge at some narrow point, then heaping up and piling over one another until the river from bank to bank was filled with ridges and diminutive mountain chains of ice. As winter advances the water falls, allowing the ice bridge to hang suspended until it breaks through its own weight, and comes down with a tremendous crash. Later in winter the Bishop started to visit the Cioquo Indians. Here it may be mentioned that traveling in the interior of Alaska is always at the extreme peril of the venturesome explorer, the Indians who are continually at war, treating all strangers with strict impartiality when once they take to the war path. This journey to the Cioquois was undertaken in dog-sleds, a style of traveling not without its disadvantages, one of which is occasioned by the dogs striking a game trail, and following it up on the full run regardless of the load behind, which is scattered in every direction. The ordinary load of a dog-sled is 500 pounds. The driver usually keeps up with his team by joggling along at a dog trot, but sometimes he treats himself to a ride. A good dog-driver can easily run 70 miles a day, one day with another—a feat to match our Westons and O'Learys. A team is made up of seven or nine dogs, always an uneven number, one taking the lead, the others harnessed in pairs. The dress worn on such expeditions is a deer-skin coat with Capuchin hood to draw over the head, fur cap, deer-skin trousers and boots. The deer-skin, dressed only enough to make it pliable, is worn with the hair outside. While among the Cioquois the travelers put up quite frequently in the *barabara*, or native hut, whose construction may be understood from the following description: On entering the *barabara* the visitor first descends a shallow pit, from the bottom of which a tunnel eight feet long conducts him to the subterranean portion of the dwelling. The hut is circular, and is sunk into the ground about five feet. The portion above the level of the ground is built of mud and is of conical form. Only one opening is provided, and this is in the apex, where it gives escape to the smoke. At night this opening is closely covered with seal-skin, and the tunnel tightly closed, so that all access to the cold, and to the air as well, is cut off. In this manner the *barabara* is made very warm, but exceedingly unwholesome. Where a hut of this description was not met with at nightfall, the travelers dug a square hole in the snow, built a rampart of branches toward the northern side, from which the wind nearly always blows, and sought repose on a couch of boughs thickly laid on the bottom of the hole. Exposed thus to Arctic cold in the open air, tea is the only beverage used by the Northerner. Strong spirits create a greater amount of heat in the system, but the reaction following leaves the traveler more than ever exposed to danger of death from freezing.

While among those people, the Bishop also formed the acquaintance of a Medicine Man, who undertook by his incantations to cure a sick child in the house where the Bishop's party were guests. Part of the performance consisted in pounding a gong with a club, and when the Bishop learned that this ceremony was to be continued all night, it need not surprise us that even the proverbial patience of the missionary became exhausted, and that *vi et armis* the Alaskan M. D. was forthwith deprived of his professional paraphernalia.

Returning to Nulato, the party started down

the river by sledge, experiencing such a degree of cold that 60° below zero was frequently registered by the spirit thermometer. On the trip the Bishop witnessed a religious ceremony which seemed to mean the worship of fire if it meant anything; and that half-frozen wretches should at length take to the adoration of fire as their salvation from the Polar cold is not very strange. Those Indians are adepts in making earthenware, some of their utensils being of a capacity to hold several gallons, and representing a very considerable advance in the potter's art. They differ from the southern Indians of the Pacific coast in their manner of disposing of their dead, which are hurried, not hurried, as among the Putes, Washoes or Diggers. They resemble the whites in having a taste for ornamenting the graves of their departed warriors; but one epitaph found by the Bishop was not calculated to stir very profound depths of woe. It had probably been picked up at some trader's camp and devoted to use as an epitaph, the finder evidently believing it to possess virtues not of this world. Fastened to a pole and placed at the head of a departed warrior, it gave "Bee hive Breakfast Bacon" as its recital of the virtues possessed by the deceased. But perhaps the most interesting fact mentioned by the reverend lecturer is the astonishing proficiency in music acquired by those savages. So far advanced are they that their arias can easily be committed to writing by our system of musical notation. Three or four of these songs were rendered word and note by his Grace, who has a fine baritone voice. In one, a warrior's funeral dirge, a mingling of grief with enology of martial prowess must have been the meaning of the words, so clearly did the air express those combined feelings. The lecturer also gave specimens of Alaskan dancing, which it appears is done principally by the women, under the eyes of their admiring lords. The dance is highly and euphratically "proper," consisting as it does of a leaning posture in which the dancer stands on one foot while she pounds the floor with the heel of the other, the toe not being moved from the floor. Even the most straight laced could have nothing to say against such "steps."

On the Aleutian island the winters are not very severe. The snow falls very deep, about 24 or 25 feet every winter. This depth is of packed snow, through which the people of the villages cut passages from one house to the other. The principal occupation of the inhabitants is seal fishing in the employ of the Northwestern Fur Co. Seals abound in enormous numbers. On St. Paul island their estimated number is 11,000,000; on St. Michael island, 5,000,000 or 6,000,000; an enumeration being an easy matter since they are not at all shy.

Texas.

The old mining districts on the San Saba river in Menard county, which were opened up and developed over a century ago by the Spaniards, are now again obtaining notoriety through the settlement of several counties in the mineral region, and it is believed that the capital which is now being interested in reopening and developing the old mines and prospecting new ones, will soon bring Texas prominently to the front as a mineral producer, as in ancient times these mines were spoken of as the richest and most productive belonging to the Spanish crown. We learn from a gentleman largely interested in the development of these mineral resources that since the settlement of Mason, McCulloch, San Saba, and Llano counties, which has but recently occurred, a great many prospect holes have been made, and the most promising "shows" are now to be seen there. Especially is this so in Mason and Llano counties. The veins are well defined and many of them of great length; the gangue generally being of gray copper, peacock, red and blue and green carbonates, oxide of copper, with copper pyrite and yellow iron pyrite, nearly all of which carry from 3 to 60 ounces silver, $\frac{1}{2}$ to 5 ounces gold, and 40 to 80 of copper. The green and blue carbonates are valuable for the copper alone—55% to 70%. One or two shafts have been sunk by private enterprise, showing a continuation of the veins and an increased value of vein matter. One shaft in Mason county, at 102 feet in depth, shows a vein 22 inches wide, filled with the ores before mentioned; this vein increased in width at the rate of one inch per foot as far as it was followed, with hard quartzite walls. It is one of a group of five, and possibly six, which promise well, and run parallel to each other, only a few yards apart. It is believed by experts that these veins at no very great depth will become one; at all events, they could each be worked from one opening on the surface. These mines are about 100 miles from a railroad depot, are surrounded by a superabundance of mountain post-oak, which makes an excellent smelting coal, and can be burned at less than 10 cents per bushel. Roads are hard, winter and summer, and the mines can be worked every day in the year. The State of Texas came into the Union by annexation, and retained the control and ownership of her vast public domain; hence there are no mining laws of the United States which apply to the mines within her borders. The lands are ceded by letters patent to individuals, giving absolute ownership to the mines, etc., upon them. For this reason prospectors have been kept out of the country, the owners of land having upon them "shows" preferring to hold them for speculation or sale at large figures.—*Investors' and Mining Journal.*

MECHANICAL PROGRESS.

Measuring Velocity of Light.

Albert A. Michelson gave before the American Association for the Advancement of Science at Saratoga, the following description of his apparatus for measuring the velocity of light. A beam of light is allowed to fall through a slit upon a rapidly rotating mirror, from which it is reflected upon a lens of great focal length, throwing the beam upon a plane mirror placed at right angles to its axis. Now, the image of the slit in this plane mirror will again act as an object which will be reflected upon the rotating mirror. While the light has traveled from the rotating mirror through the lens to the plane mirror and back again, the rotating mirror will have changed its position so that the returning image of the slit will not be reflected to the place from which it came, but will move from it. When the rotation of the mirror becomes sufficiently rapid, then the flashes of light will produce a stationary image, which is deflected in the direction of the rotation, and through twice the angular distance, described by the mirror during the time required for the light to travel twice the distance between the mirrors. By accurately measuring the deflection, the distance between the mirrors and the number of revolutions made by the revolving mirror, all the elements necessary for the determination of the velocity of light would be given. An important point was to insure regularity in the rotation of the mirror, and this Mr. Michelson achieved with the aid of the apparatus devised by him. The revolving mirror was set in motion by a blast of air passing through a regulator, and acting upon a species of turbine wheel attached to the axis of the mirror. The supply was varied by a valve.

To regulate and measure the speed of rotation, a tuning fork, bearing on one prong a steel mirror, was employed. This was kept in vibration by a current of electricity from five gravity cells. The fork was so placed that the light from the revolving mirror was reflected to the piece of plane glass in the eyepiece, thence reflected into the eye. When fork and revolving mirror are both at rest, the eye sees an image of the revolving mirror. When the fork vibrates, this image is drawn out into a band of light. When the mirror commences to revolve, this band breaks up into a number of moving images of the mirror; and when, finally, the mirror makes as many turns as the fork makes vibrations, these images are reduced to one, which is stationary. This is also the case when the number of turns is a sub-multiple. When it is a multiple, or a simple ratio, the only difference is that there will be more than one image. The electric fork made about 123 vibrations per second. No dependence was placed upon this rate, however, but at each set of observations it is compared with a standard U_2 fork, the temperature being noted at the same time. In making the comparisons the beats were counted for 60 seconds.

The apparatus for measuring the deflection consisted of a screw with divided circle, on which a carriage supporting the eyepiece traveled. The deflection was read on a scale and the circle of the screw. The distance between the revolving and the plane mirror, measured with steel tape and corrected, was found by the mean of several observations to be 1986.35 meters. The rate of vibration of the standard fork was 256,070 vibrations per second at 65° F. From these data Mr. Michelson found the velocity of light, from an average of 100 determinations, to be in vacuo 299,823 kilometers per second, or taking one kilometer at 3280.87 feet, 186,293.5 miles.

NEW ROTARY ENGINE.—A French inventor, Claude Jobert, has lately conceived the idea of combining the actions of the Woolf engine so as to obtain therefrom a direct rotary motion without the intervention of a connecting rod, and which should have no dead-point. The Woolf engine, as is well known, consists of two cylinders—a small and a large one. The first of these receives steam at full boiler pressure, the second allowing the same volume of steam to expand after it has done its work in the first cylinder; or else it is composed of a small cylinder, placed between two larger ones, in which latter the expansion of the steam takes place. Mr. Jobert's improvement is designed not only to avoid the numerous escapes of steam which occur in the rotary engines at present in use, but also to utilize the expanded steam. For this purpose he has placed the smaller cylinder within the piston of the large cylinder and at right angles to the latter. By this means a quadrangular motion is produced, which communicates a direct circular movement to the shaft, not by the suppression of the rectilinear motion, but by a combination at right angles of the two rectilinear motions. In the center of the piston of the large cylinder is another and smaller piston, which works vertically within it. These two pistons are crossed transversely by a cranked shaft. The result of this combined movement of the two pistons is, that a dead-point only occurs in one cylinder at a time, and at that moment the action of each of the pistons is supplemented by that of the other, since they both act together on the same crank. They thus communicate a uniform circular motion, without any dead-point, and without any intermediate connections. This engine is capable of

working either with or without expansion and in either direction.—*Universal Engineer.*

RECTANGULAR BORING MACHINE.—At one of the recent meetings of the Franklin Institute, Dr. Robert Grimshaw exhibited a sample of the work done by J. Hall's rectangular hole-boring machine. As this mechanical paradox attracted considerable attention at the Paris exhibition, the readers of the PRESS will be interested in a brief explanation of it. The drill has for section an equilateral triangle. The tool-holder of a special shape, having a screw at the upper portion, then a rectangular section; then a round section of a given diameter; then another section of the same shape, but of greater diameter. There is a hollow rectangular sleeve, somewhat larger and narrower than the rectangular section. A slight horizontal and vertical movement can be thus obtained. This sleeve varies in size and amount of play according to the work to be done. When the tool is in position it is guided by a steel plate, which has a hole corresponding to the one we wish to bore. In turning, the tool occupies various positions, the cutting portion following the exterior contour of the rectangular guiding plate. If a pressure is exerted upon the tool, the boring will commence producing, as desired, a rectangular hole. If any portion of the tool be considered during its rotation, it will be found that the loci of the same represent most interesting curves of the third and fourth orders.

REVERSAL OF MOTION WITHOUT GEARS OR BELTS.—In 1853 M. Claparde, Roux and Delille attempted to produce opposite revolutions of two parallel arbors by means of a Watts parallelogram, but these experiments were not satisfactory. Charles Bourdon has lately introduced a contrivance which is based upon the two following theorems: 1. If two cranks, of any length and initial position, turn with the same angular velocity, the point which divides the line of variable length, which joins their extremities at each instant, describes a straight line parallel to the bisectrix of the angle of the two cranks. 2. When the two cranks are equal, the projection of the joining line on the bisectrix preserves a constant length. By means of an ordinary slide, M. Bourdon compels the middle of the system to take a rectilinear movement. Then, by means of two reciprocating Peaucellier cells, or even without the use of cells, if one extremity of the crank is allowed a slight play, two arbors may be easily connected so as to turn in opposite directions and to avoid any dead point.—*Bull. de la Soc. de l'Enceur.*

A REMARKABLE REPEATING RIFLE.—An invention has been patented by one of the late chief mechanics of the small arm manufactory at Steyer, in Upper Austria, which is attracting much attention in Austria and Germany, since, should its practical application prove feasible, it will add very greatly to the power of musketry fire. The invention consists of an apparatus, described as very simple in design and construction, by which an ordinary breech-loading rifle can, whenever it may be desired, be temporarily converted into a repeating arm. The apparatus holds 10 cartridges, and can be carried by the soldier in his pocket. When necessary it can be fitted on the rifle in a moment, when the 10 rounds can be fired just as rapidly as the same number of cartridges can be discharged from any magazine rifle. The inventor has submitted his apparatus, which has been recently materially simplified and improved by Werndl, the well-known small arm manufacturer to the Imperial War Ministry, and a series of experiments are, it is stated, to be shortly carried out with it.

MINERAL PROSPECTING AND RAPID BORING. The Cumberland Diamond Boring Company have been at work since the latter part of last year in the neighborhood of Dronagan, Ayrshire, putting down boreholes to prove the coal field of that district for Messrs. J. Galloway & Sons, of Kilmarnock. Holes 1,254 feet and 832 feet deep have been completed, and satisfactory samples of the strata obtained not only from the rocks, but also from the coal seams passed through. In the whinstone, as much as 15 feet per day of six-inch hole was bored, whereas, in the ordinary way, it is difficult to bore a 2½-inch hole at a greater speed than 6 inches per day. The value of this system of boring is not generally known, as not only is a rapid speed obtained, but always reliable section of the rocks and good solid samples of the coal. We understand this company is now boring for the Shotts Iron Company, near Roslin, and are largely employed in boring wells for water supplies as well as prospecting for minerals.

LEAF-TURNING MACHINE.—Herr Carl Taense, of Berlin, has invented improvements in machinery for turning over the leaves of music. They consist of several arms, each fastened to and actuated by a spring fixed in a case, to which also is affixed a drag-spring for giving power to turn over the arms, which are furnished with guides or pieces. Each arm and its guide is applied to and embraces a sheet of music or the leaf of a book. At the bottom of the apparatus is a finger-plate or ledge, which is connected by one or more levers to the spring cases and certain ratchet or catch-pins, so that when the finger-plate is pressed the spring is released and turns over an arm with its leaf, and so on. Instead of a finger-plate a pedal-plate may be used by a slight alteration of the operating levers. The various parts may be of metal or wood, or of both combined.

SCIENTIFIC PROGRESS.

ORNAMENTING GLASS WITH METALS.—Parties in France have invented and patented a new process for ornamenting glass with metals. For the golden bronzing of glass, instead of using, as at present, the air or vapor by which glass is now blown in molding or shaping it by hand. They employ a suitable reducing gas, such as pure hydrogen gas or coal gas, for the purpose of reducing metallic oxides or salts added in the composition of the glass, and thereby metallizing the interior surface of the glass. This may be done of all shades or colors, according to the composition of the glass. The oxides may be any of those generally used in glass working, for instance, oxides of copper, which, when reduced as above mentioned impart a golden or bronzed aspect to the glass. This metallizing process may be applied not only in the manufacture of all kinds of articles of glass or crystal, but also to stained window glass, glass plaques, or tile for mural or other decoration, reflectors, lighthouse lenses, and glass used in lighting apparatus generally. The most attractive article to which they are turning their attention is the Corinthian chine metallique, which is produced by enclosing a layer of gold or other leaf between two layers of glass, subsequently expanding the glass so as to break up the metal into infinitesimal fragments, the result being a kind of aventurin glass, resembling the spangled enamel found at Corinth.

COMBUSTIBLE DUST.—There are many combustible dusts, which are very dangerous. Zinc dust is imported in considerable quantities for use in certain branches of industry. It is a gray powder, and extremely fine. Great care should be taken to keep moisture away from it, for when moisture comes in contact with it it will readily oxidize—a process which is attended by a great rise in temperature—and the hydrogen gas which is liberated may take fire. This has often been the true cause of apparently mysterious ship and factory fires. Dry coal dust in mines will readily explode when ignited. These sources of disaster are not properly guarded against in America. It would be difficult to free mills and factories from the dusts that are constantly generated inside them. But they might be ventilated by strong air currents to carry off all the dust. Keep workmen from lighting their pipes and keep lamps and gas-lights out of the building. A match, a lantern, sparks produced by friction, any source of fire may produce a disastrous explosion.

SPECTROSCOPIC DETECTION OF ERGOT IN FLOUR.—The following method of detecting the presence of ergot in meal by spectroscopic analysis has been devised and practiced with success by M. J. Petri. He boils about 20 grammes of the suspected meal several times successively in alcohol, pouring off the spirit after each operation till it has lost all yellow tinge and comes away perfectly colorless. About 20 drops of dilute sulphuric acid are added to the exhausted meal, which is then well stirred up and thrown on a filter. The filtrate will now assume a red color if ergot be present, owing to the fact that this latter contains an easily soluble red coloring matter, which it readily yields in alcohol or ether. When examined in the spectral apparatus, the filtrate, even in an extremely weak solution, shows two well-defined absorption bands, one of which lies in the green between E and F, and the other in the blue between F and G. M. Petri is now engaged in an attempt to find a method of quantitatively determining the ergot by the intensity of the red color in the filtrate.

NEW THEORY OF TERRESTRIAL MAGNETISM.—Professors Perry and Ayrton have proposed the theory that the revolution of the earth beneath the electrical charge originally and at all times present in the atmosphere may and is sufficient to account for the magnetism of the earth. They have submitted the matter to calculation, and find that the difference of potential between the earth and space necessary to produce a distribution sufficient to produce the observed magnetic effect can be represented by 54,000,000 Daniell cells. They prove, according to this theory, that "if the earth be electrified, it must, from its very rotation, quite independently of all other bodies in the universe, be magnetic; and if it consist of a shell of iron, thick or thin, then that the law of distribution of magnetism produced by this electrical charge in mechanical rotation, will be identically that given by Biot; and, lastly, if the earth were wholly of iron, a difference of potentials of about 54,000,000 volts between it and space would be sufficient to produce the necessary amount of charge.—*Phil. Mag.*

LACUSTRINE RELIC.—M. Morel Fatro, who is conducting some extensive explorations at the lacustrine station of Corcelettes, Canton Vaud, announces the discovery of a large canoe in an excellent state of preservation. It is formed of a single pine log 32 feet long and 2½ feet wide; and though the stern is slightly damaged, the bow, which is carved and ornamented, is perfect. This interesting find will be placed in the museum of Lausanne, which now contains the richest collection of lacustrine relics in Europe.

OCCCLUSION OF HYDROGEN BY COPPER.—Johnson has re-examined this result deduced by him from his earlier experiments, that metallic copper occluded an amount of hydrogen which might cause serious error in organic analysis; this result having been questioned by Thudichum. The copper to be tested was oxidized at the blowpipe, reduced in hydrogen, allowed to cool in that gas, the H displaced from the tube by dry air, the metal re-oxidized in a current of dry air, the water produced being collected in a weighed tube containing pumice moistened with sulphuric acid, special precautions being taken to exclude extraneous moisture. It was found that this occlusion actually took place, and that the pulverulent metal formed from the oxide reduced on the surface of the copper was most active, the amount occluded diminishing progressively as the metallic powder becomes denser by successive heating. A carefully conducted experiment showed the occlusion of 0.035 gram of hydrogen by 100 grams of copper. But curiously enough, it appeared that the finest precipitated copper oxide yields a finely divided metal on reduction, which does not occlude hydrogen. Moreover, the author found that the copper thus hydrogenized, reduced potassium chlorate to chloride. Heating alone in a vacuum does not set free the gas. The author therefore concludes that it is unsafe to employ copper freshly reduced in hydrogen for the reduction of oxides of nitrogen in organic analysis unless the metal be previously ignited in nitrogen gas.—*J. Chem. Soc.*

GLASS WICKS FOR LAMPS.—Messrs. Voubriel and Beck, of Hanau, have invented a patent form of lamp wick, made entirely of glass, the use of which they claim to be attended with very considerable advantages. It is chiefly intended for petroleum and spirit lamps. A series of experiments have been made with it at the instance of the *Technisches Organ für Gewerbe und Haushaltung*, and the report given in its columns is decidedly favorable. The flame clings closely to the wick, so that lighted lamps may be carried about without fear of their being extinguished by sudden drafts; moreover, no sparks are liberated from it. With an equal amount of this wick turned up, a much brighter and clearer light is obtained than where cotton ones are used. The smoking is greatly reduced, and at least 10% of oil is saved. There is scarcely any waste of the wick itself, and the troublesome trimming and cutting to which lamp burners are accustomed, is altogether needless, for no portion of it is carbonized. Used in spirit lamps it greatly increases the heat of the flame, and finally it can be produced and sold at a very cheap rate.

CHANGE OF VOLUME IN IRON.—At the recent meeting of the British Association at Sheffield, Mr. T. Wrightson read some observations on the change of volume in iron when passing from the liquid to the solid state. He argued against the prevalent idea that cast-iron when cold would float in its own fluid and declared it a fallacy. Cast-iron spheres of various sizes, lowered into a ladle of molten iron invariably went below the metal for a few seconds, then rose to the surface, and continued rising gradually until their maximum expansion had been reached. This rapid rising to the surface was the result of an expansion in the ball when heated by contact with the fluid metal. It is customary to assume when the iron was observed to sink that the velocity of its fall carried it down, neglecting the fact that the volume of the ball, and therefore its conditions of flotation had been altered by the heat during the time of its immersion.

TEMPERED GLASS.—According to the *Glashütte*, tempered glass, though it has fallen into discredit in Germany, is in growing demand in France and Holland, as is proved by the establishment of new works and the improvement in the process. At Choisy-le-Roy the glass is tempered in a bath of margarine (a by-product of the artificial butter manufacture). At other establishments saline baths are in use. The bursting of tempered glasses may be due either to the original mixture having been melted at too low a temperature, or to the fact that the heat of the tempering bath is not duly proportioned to the weight and thickness of the articles.

COLORS PHOTOGRAPHS.—M. Cros prepares three photographic impressions of any object by sifting the light through solutions which will respectively arrest the green rays, the yellow rays, and the violet rays. The impression from which the green has been excluded, if developed under green light, will appear intensely green at points where the original was the greenest, and pale green or black at the green points where the green was mingled with other colors or was entirely absent. By combining the three negatives, and superposing the images by the help of reflecting prisms, he obtains an approximate solution of the fixation of colors by photography.—*La Nature.*

NEW MEANS OF ILLUMINATION.—The applications of phosphorescence are not confined to the illuminated dials of watches, nor even to phosphorescent paint. It seems it may be applied to the illumination of a room. At the late exposition at the Palais d'Industrie, at Paris, a dark room was prepared with phosphorescent window panes, which afforded a tolerable light, doing away with the necessity of any other light.

Mineral Veins.

[A contribution to the History of Mineral Veins, by JOHN ARTHUR PHILLIPS, Esq., F. G. S., Read April 30th, 1879, before the London Geological Society.]

Certain districts in California are remarkable for their hot springs, and in some of the counties included between the 38th and 40th parallels, and consequently north of the city of San Francisco, sources of this description are of frequent occurrence, that, when viewed from elevated ground, almost every valley is seen to be more or less occupied by wreaths of steam rising from a flow of highly heated waters.

The vents giving issue to these heated waters usually evolve carbonic acid, which is frequently accompanied by various sulphurous gases; such waters are generally alkaline, containing carbonate and sulphate of sodium, as well as, occasionally, alkaline borates. They generally give rise to abundant local incrustations of either silica or calcite, usually more or less mixed with free sulphur. These deposits of sinter often extend in nearly horizontal layers, to a considerable distance from orifices from which the waters issue. When water is ejected from such vents in the form of steam and spray only, while gases are abundantly given off, and large amounts of sulphur deposited, the aperture becomes a solfatara.

One of the largest known deposits of sulphur in California, occurs in Laks county, a mile beyond the ridge which bounds Borax lake on its northeastern side, and is many acres in extent.

This "Sulphur Bank," as it is called, is composed of a much decomposed volcanic rock, traversed by numerous fissures, from which gases, steam and water, either in the form of spray or of vapor, constantly issue; and upon and throughout the entire mass sulphur has been deposited in such large quantities that, at a short distance, the whole appears to consist of that substance. In the immediate neighborhood of this solfatara are springs which give off carbonic acid, and of which the waters contain carbonates of sodium, and of ammonium, chloride of sodium, borax, etc.

The sulphur from this locality always contains a small amount of mercury in the form of cinnabar, and the sides of the fissures in the volcanic rock through which the gases and water make their escape are sometimes coated with gelatinous silica, beneath which is a layer of chalcedony resting upon a stratum of crystalline quartz. This siliceous deposit frequently contains pyrites and a notable percentage of cinnabar, or is stained by a tarry hydro-carbon; while the crystals of quartz often enclose liquid cavities in which the usual bubbles are distinctly visible.

In the year 1866, I visited Borax lake, and the neighboring sulphur bank in company with Mr. R. Oxland, of Plymouth, who was the first to call attention to the presence of cinnabar in the sulphur of this locality; and in 1868 I published in the *Philosophical Magazine*, a paper advocating the probability of certain mineral deposits having been the result of hydrothermal or solfataric action.

For many years subsequent to my visit this solfatara was worked as a source of sulphur only; but during these operations so large an amount of cinnabar was discovered, both in the decomposed basaltic rock and in the cretaceous strata through which it has been erupted, as ultimately to lead to the opening up of the cooler portions of this sulphur bank as a mercury mine. This has long yielded large quantities of quicksilver, and affords a striking and instructive example of a recently formed mineral deposit resulting from agencies still somewhat actively in operation.

I have specimens of this cinnabar and also a specimen of a thin section of recently formed quartz from the face of a fissure in the decomposed basaltic rock. Many years since Mr. Oxland found a notable amount of silver in the sinter-like deposit from a hot spring in the county of Colusa, and Prof. Whitney previous to 1865, had been shown at Clear Lake some peculiar and interesting specimens of water-worn cinnabar enclosing specks of gold, said to have been found near Sulphur Springs, in the same county.

These, from being water-worn, and from not having been found *in situ*, had necessarily lost a certain portion of the interest which would otherwise have been attached to them; but through the kindness of Mr. Melville Attwood, of San Francisco, a Fellow of this Society, I was enabled to procure a specimen of cinnabar from Colusa county, which, having been formed upon one of the surfaces of a fissure, has subsequently become covered by a brilliant deposit of metallic gold.

Steamboat Springs, in the State of Nevada, are situated near the base of a volcanic hill, seven miles, in a direct line, northwest of Virginia City, and of the famous silver mines on the Comstock lode.

The rock at this place is traversed by several parallel fissures, which either give issue to heated waters, or simply throw off clouds of steam. The most active group of these *crisees* comprehend five parallel longitudinal openings extending, nearly in a straight line, for a distance exceeding 1,000 yards, their general direction is nearly north and south, and all of them are included within a zone 200 yards in width. These *crisees* are sometimes filled with boiling

water, which overflows in the form of a rivulet; while at others violent ebullition is heard to be taking place a short distance below the surface. These fissures are lined with a siliceous incrustation which is being constantly deposited, while a central longitudinal opening allows of the escape of gases, steam, and boiling water.

The water is slightly alkaline, and contains carbonate of sodium, sulphate of sodium, common salt, etc. Carbonic acid escapes nearly along the whole line; while sulphureted hydrogen is evolved and sulphur deposited at certain points. The fissures, which appear to have been subjected to a series of repeated widenings, such as would result from unequal movement of their walls, are lined, sometimes to a thickness of several feet, by incrustations of silica of various degrees of hydration, containing hydrated ferric oxide, and exceptionally, crystals of iron pyrites. This silica exhibits the ribbon-like structures so frequently observed in mineral veins, and when examined under the microscope is observed to consist of alternate amorphous and crystalline bands, sometimes enclosing druses lined with crystals of quartz.

At a distance of nearly a mile, in a westerly direction, from the locality above described, is a second group of fissures in every respect similar to those at Steamboat Springs, excepting that they are no longer traversed by hot water, although still at various points giving off steam and carbonic acid. Towards the southern extremity of the principal fissure of this group, the siliceous deposit extends considerably beyond the edge of the cleft, and has accumulated to a distance of some 90 yards on each side of the opening.

The silica of this deposit is sometimes chalcedonic and contains nodules of hyalite; by far the larger proportion of it, however, although somewhat friable, is distinctly crystalline, the crystals containing numerous liquid-cavities and exhibiting the usual optical and other characteristics of ordinary quartz. Besides oxides of iron and manganese, this quartz contains small quantities of iron and copper pyrites; and in a paper on the Gold Regions of California, published in the *Annales des Mines*, in 1863, Mr. Laur states that he had found it to contain distinct traces of gold. With regard to these deposits, this gentleman remarks that, so far as auriferous quartz veins are concerned, Steamboat Springs appear to place before us a sort of practical verification of the theory which regards a certain class of metalliferous deposits as being produced by mineral waters in the fissures through which they circulate.*

For many years local attention does not appear to have been directed to this portion of the Steamboat valley; but in the year 1878, this older fissure was opened by a tunnel to a depth of 50 feet from the surface, and the veinstone was found so impregnated with cinnabar as to yield large quantities of mercurial ore of considerable commercial value.† At this depth the temperature was not sufficiently high to cause inconvenience to the workmen, and five samples of the ore subjected to assay gave an average of 2.90% of mercury.

Samples taken from the nearly horizontal flats produced by the overflow of water, yielded, on the contrary, traces only of that metal.

Steamboat Springs thus afford another striking example of the recent formation of a considerable metalliferous deposit by the agency of hot springs; and I am again, through the kindness of Mr. Attwood, enabled to lay before the Society a specimen of cinnabar from this place.

In further illustration of this subject, I may mention the deposit of bright red cinnabar in a brecciated vein mass, near the hot springs, at Calistoga, at the foot of Mt. St. Helena. Here fragments of an amorphous siliceous rock are cemented together by crystallized quartz, showing distinct lines of accretion, and throughout this minute granules of sulphide of mercury are plentifully disseminated. A hand specimen and a thin section of this veinstone are on the table.

The great Comstock lode is, as before stated, situated in a volcanic district seven miles southeast of Steamboat Springs, has a nearly similar orientation, and is enclosed between walls either of porphyry, or of diorite on the one side and of porphyry on the other. This vein, of which the gangue is chiefly silicious, although calcite is also sometimes present, was first attacked by the miner in the year 1859, and since that time has yielded silver and gold to the estimated value of above £60,000,000.

The temperature of the waters issuing from mines worked upon the Comstock lode has always been somewhat high, but it was not until they had attained a very considerable depth below the surface that the workmen first became inconvenienced by the extraordinary heat. At their present greatest depth (2,660 feet) water issues from the rock at a temperature of 157° Fahr. (70° C); and according to Prof. John A. Church, of Ohio, who has recently published a valuable paper on the heat of the Comstock mines, at least 4,200,000 tons of water, are now annually pumped from the workings at a minimum temperature of 135° Fahr.‡

He also estimates that to elevate such a large volume of water from the mean temperature of the atmosphere to that which it attains in the mines, would require 47,700 tons of coal. In addition to this, however, 7,859 tons of coal would, he calculates, be required to supply the heat absorbed by the air which passes along the

various shafts and galleries through which it is diverted for the purposes of ventilation.

It follows, therefore, that to develop the total amount of heat necessary to raise the water and air circulating in these mines from the mean temperature of the atmosphere to that which they respectively attain, 55,560 tons of coal, or 97,700 cords of firewood, would be annually required.

Mr. Church, in his paper, quotes four distinct analyses of waters from the Comstock lode taken at different depths; these, as might have been anticipated, vary somewhat as to the relative proportions of the various substances present; but they contain on an average 42.62 grains of solid matter to the gallon. Of this amount 20.74 grains are calcic sulphate, 12.13 grains carbonate of potassium, 4.85 grains carbonate of sodium, and .66 grains chloride of sodium.

In order to ascertain approximately, to what extent the production of the large amount of heat absorbed by the water may be ascribed to oxidation of sulphur and iron, the Professor first calculates the quantity which would be developed by the oxidation of pyrites equivalent to the calcic sulphate in solution. But having found that this amounts only 1-143d part of that required, he subsequently seeks another solution for the difficulty, and without bringing forward any calculations in support of the hypothesis, attributes this enormous development of heat to the kaolinization of feldspar contained in the adjacent rocks.

If, however, we apply to the kaolinization of feldspar for the heating of water alone, a somewhat similar line of reasoning to that adopted by Prof. Church regarding the oxidation of pyrites, we shall find that this source of heat is also utterly inadequate to produce the effect observed.

The average proportion of alkalis contained in the rocks of the district is 6.40%; while the mean of the published analyses gives 11.30 grains of alkalis in 58,373 grains (U. S. gallon) of mine water. It consequently follows that the 4,200,000 tons of water annually pumped out of the workings must contain 813 tons of alkalis, and that, as these are present in the rocks in proportion of 6.40%, the feldspar in 12,703 tons of rock must be annually kaolinized, and the whole of the alkalis removed in the solution.

The amount of rock in which the feldspar has been kaolinized being 12,703 tons, and the number of tons of water pumped out of the mines 4,200,000, it follows that

$$\frac{4,200,000}{12,703} = 330,$$

is the number of tons of water heated by each ton of altered rock.

In order, therefore, that one ton of rock should be enabled to heat 330 tons of water only 1° Fahr., and if the specific heat of these rocks be taken at .1477, which is that of blast-furnace slags, it would require to be heated by the kaolinization of its feldspar to a temperature above that of molten gold. Consequently to raise the water 85°, or to a temperature of 135°, at which it issues, the kaolinization of the feldspar in each ton of rock would require to elevate it to an extent we are unable to estimate, since there are no means of ascertaining the specific heat of bodies at such enormously high temperatures. It is therefore evident that the kaolinization of feldspar is no more than the oxidation of pyrites, an adequate cause to account for the heat of the Comstock lode; and in the present state of our knowledge we cannot regard this phenomenon otherwise than as being a last trace of volcanic activity. Prof. Church adduces the high temperature of the waters of Steamboat Springs as a proof that the rocks of this region are capable of producing sufficient heat to raise large quantities of water to the boiling point; but these springs give rise to an evolution of sulphureted hydrogen and to a deposition of sulphur, which cannot be results of the decomposition of feldspar. It is probable that the Comstock lode and hot springs in Steamboat valley may have had a somewhat similar origin, but, in the case of the former, volcanic agencies are no longer actively in operation, while both sulphur and sinter have long since been removed from the surface by denudation.

A COMPANY in Westfield, Mass., have, it is said, after much experimenting, perfected a wheel of remarkable cutting qualities, being composed of corundum, the next hardest substance in nature to the diamond. In a scale of 12, rating the diamond at 12, corundum stands at 11; while emery averages at 8½ in hardness. The difficult problem, attempted by so many, of finding a base strong enough to hold corundum without interfering with its cutting qualities, has, it is thought at last been solved by a happy combination of materials and an ingenious use of the process of vitrification. The cost of the corundum wheel is only about 25% more than that of the ordinary emery wheel.

A PATERSON (N.J.) manufacturer within a month has bid on no less than 100 locomotives, which is the largest number he has seen proposed for since the panic, and he has specifications on hand for at least 50 more. At the Rogers Works they have all they can do and are far behind with their orders. If they had shop room they could employ 1,000 more men than they now have. The Danforth Works are also driven to their utmost capacity, with a prospect that they will be further pushed before the end of another month.

Utilization of Furnace Gases.

Researches have been undertaken from time to time to ascertain the composition of gas collected in high-temperature furnaces employed in working iron, and in many metallurgical operations. The matter has excited the attention of the French Academy of Sciences, before which L. Cailletet presented the matter some years ago. The matter is fully treated in the *Annales des Mines*, Vol. XIV., p. 559, and reappears with renewed interest in view of the late rapid developments in the direction of the utilization of sulphides as fuel in the Holloway process, and the use of gas in metallurgical operations. M. Cailletet based his researches upon the remarkable labors of St. Claire Deville on the subject of dissociation, which admitted of the interpretation of a large number of metallurgical phenomena until then inexplicable. Deville showed that it is necessary to quickly cool the gas at the moment of collection in the hearth, to avoid combination of dissociated elements.

This is effected by collecting this gas in a thin copper tube, about 0.02 inch diameter, which is connected within one of the branches of a larger U-tube of the same metal. A rapid current of cold water courses through the annular space between the two tubes. One end of the straight tube pierces the wall of the U-tube in the curved part, and is connected to an aspirator. The composition of the gases collected in this apparatus entirely differs from the results given by Ebelen, who slowly aspirated the gases without regard to the recombination of their dissociated elements. Gas collected as described, on the sole of a refining furnace near the grate, contained per cent:

Oxygen.....	13.15
Carbonic oxide.....	3.81
Carbonic acid.....	1.04
Nitrogen (by difference).....	82.50

The aspirator-flask was filled with fumes of finely divided carbon, the color of which (by transmission) is exactly complementary to that of the flame of carbonic oxides. The gases issuing from these furnaces are usually directed beneath the boilers. By contact with the sides of the passages, the gases are rapidly cooled, and they are completely extinguished after passing a distance of 15 to 20 yards. Analysis shows that they contain, per cent:

Oxygen.....	7.65
Carbonic oxide.....	3.21
Carbonic acid.....	7.42
Nitrogen (by difference).....	81.72

The quantity of oxygen then has diminished nearly one-half, not by burning the carbonic oxide, the proportion of which is but slightly altered, but by consuming the finely-divided carbon. The quick cooling prevents this reaction.

M. Cailletet believes it will be interesting to learn whether it is not possible to utilize these gases that are regarded as waste, and has recently instituted, in his works at St. Mark, some experiments which have shown that the gases are easily relighted by passing them over a hearth, at the same time reducing their velocity. The heat developed attains a clear red, and may be employed in brick or lime kilns, or in the tempering of sheet-iron and wirs. His conclusion from his experiments is that the gases issuing from metallurgical furnaces still contain, even after their passage under steam boilers, an important quantity of combustible principles, that they are easily re-ignited and nearly completely burnt.

PATINAGE OF LOCOMOTIVES.—Sig. P. Oppizzi finds that the diminutions of resistances which are not followed by an equal reduction in the motive force produce an acceleration in the rotative movement of the wheels, which cannot be wholly transformed into an acceleration of the locomotive, and therefore causes slipping. He has given some experimental formulae which, although not so complete as desirable, show the importance of a more careful regard to the relation between the motive force and the adhesion of the wheels. This relation has been too much overlooked by engineers, who have sought to give increased pressure to the steam, and to work it under too great expansion in order to obtain some ideal economical advantage.—*Il Politecnico*.

News has reached Rico that on Red Mountain, about eight miles from the upper Rio San Miguel and seven miles from Ouray, and about the same distance from Silverton, carbonates have come to the light of day. They have been assayed, and run from 40 to 100 ounces to the ton.

An extensive vein of iron ore, carrying 60% of mineral has been found near Godfrey Station on the Kansas Pacific. A fine vein of coal is being developed in the same vicinity by the Union Pacific Company.

A CONTRACT for 100 iron bridges for Coeta Rica, South America, for the road from Punta Arenas to San Jose, and thence to Port Limon, has been awarded to Mr. Charles Snyder, of Paterson, N.J.

PROF. HAYDEN and others estimate that from 50,000 to 65,000 square miles of Montana's area are underlaid with coal. Several of the measure are yielding an excellent quality of fuel.

* *Annales des Mines*, 1863, p. 423.

‡ "The Heat of the Comstock Mines," by John A. Church, M. E. Presented to the American Institute of Mining Engineers at Chattanooga meeting, May, 1878.

THE ENGINEER.

Pneumatic System of Raising Minerals from Mines.

A new system of raising coal has been introduced in the Saosae-et-Loire district of the central coal fields of France, at the Hottinguer shaft of the Epinac collieries. The pit is now 656 yards in depth, it is intended to be sunk to the depth of 1,093 yards. The pneumatic tube is 63 inches in diameter, 659 yards in height, and its weight is 345 tons, being constructed of wrought iron (5-16 inch plates) in lengths of 4 feet 3 inches bolted together. The joints are made with india-rubber rings one-quarter inch thick. The tube was completed in July, 1876, and has been in operation since that time to the present. That part of the tube in which doors are placed is of cast iron. At each loading and discharging place there are three doors in the tube corresponding to the height of three coal tabs apart, mine tubs are placed one above the other in the cage within the tube. When the cage is in the first position, the first, fourth and seventh tubs are opposite to the doors; when lowered the light of a tub to the second position the second, fifth and eighth tubs are opposite to the doors, and when lowered again the height of a tub to the third position, the third, sixth and ninth tubs are opposite to the doors. It will thus be seen that a train of nine tubs are placed one above the other in the cage. The latter has two pistons attached to it, one at the top another at the bottom. These pistons work in the 63-inch tube extending the whole depth of the shaft, the cage being raised or lowered by making a partial vacuum above the piston and cage, for which air pumps are provided.

The arrangement may consist of only one tube, as in the present instance, in which one cage alternately descends and rises with the load, or it may consist of two tubes, in one of which a train of empty tubs descend at the same time that a train of full ones is raised in the other. When two tubes are adopted, the air pumped from that where the full train is being raised is delivered into the other tube where the empty one is descending.

In the Hottinguer shaft the air of the mine filling the lower part of the tube as the cage rises is blown out at the surface through an escape pipe as the cage descends, and to some extent assists the ventilation. The cage is kept in any position by stops or keys worked from the outside, and may be lowered or raised at the stations to bring the tubs opposite to the doors. This is done by admitting air over it, or by opening a communication between the tube above the cage and the air-pumps. The cage is stopped gradually at the ends of its travel by the cushion of air at the closed ends of the tube. To allow of stopping at intermediate levels, and also to guard against accident, a sliding partition is fitted in the tube immediately below each station, excepting that at the bottom, which is open so long as the cage is below, but is closed after it has passed.

The position of the cage with its pistons during the ascent or descent is indicated by several barometers placed in the engine-house, showing the pressure of the air within the tube at points 109 yards apart. As the pressure below the cage is equal to atmospheric pressure, whilst a partial vacuum is made above it, the barometers indicate at once whether the cage is above or below the point at which each one is put in communication with the tube.

To make the pistons air-tight, even at the doors, where the tube is not cylindrical, the piston above the cage is made in two parts or planes, with a space between them greater than the height of a door, but less than the distance between the two doors. The two pistons are packed with leather. The tube is lubricated with soap and water mixed with oil.

The air cylinders are two, 63 inches in diameter, 6 feet stroke, driven by an engine formerly used in winding. This machinery is only temporary; larger engines are being constructed. The weight of coal raised in each lift is 3 tons; the gross weight of the train laden is 6 tons. The vacuum made within the tube is equal to a column of mercury 9.4 to 9.3 inches in height. The speed of the train is about 19½ feet per second; friction is slight, and the leakage of air past the piston is very little.

The work performed in lifting the coal on the pneumatic system is stated to be 28% of the indicated horse-power of the engine. With the same engine when used for winding by ropes, the work did not amount to more than 16%. Engines are being constructed of 730-horse power to work the air-pumps and exhaust from the tube. With these, 4½ tons of coal will be raised at each lift; the gross weight of the laden train will be 9½ tons. The consumption of coal for the boilers of the new engines, lifting from a depth of 1,093 yards, is estimated to be 10% of the coal raised if ropes were used, but with the pneumatic system and single tube only 3%. This would give a lessened consumption of 157 pounds of coal per ton to be raised.

The new engines and air-pumps may be utilized, it is suggested, in producing a partial vacuum in the workings of the mine by closing all entrances to it when the workmen are on the surface. Fire-damp may thus be more thoroughly drawn out than it is when there is a considerable fall in the atmospheric pressure as indicated by the barometer. The mine may afterwards be cleared and pure air put into circulation before work is again commenced.

USEFUL INFORMATION.

Fusible Metals.

Of mixtures of metals which become liquid at temperatures at or below the boiling point of water, there are several known, some of which are placed in convenient order, as follows:

1. D'Arcet's: Bismuth, 8; lead, 5; tin, 3 parts. This melts below 212° Fah.
2. Walker's: Bismuth, 8; tin, 4; lead, 5; antimony, 1 part. These metals should be repeatedly melted and poured into drops, until they can be well mixed, previous to fusing them together.
3. Onia's: Lead, 3; tin 2; bismuth, 5 parts. Melts at 197° Fah.

4. If, to the latter, after removing it from the fire, one part of warm quicksilver be added, it will remain liquid at 170° Fah., and become a firm solid only at 140° Fah.

5. Another: Bismuth 2; lead, 5; tin, 3 parts. Melts at boiling water.

Nos. 1, 2, 3 and 5, are used to make toy spoons, to surprise children by their melting in hot liquors. A little mercury (as in 4) may be added to lower their melting points.

Nos. 1 and 2 are specially adapted for making electrotypo molds. French cliché molds are made with the alloy No. 2. These alloys are also used to form pencils for writing, also as metal bathis in the laboratory, or for soft soldering joints. —Scientific American.

VARNISH FROM YELLOW AMBER.—The lacquers made from these materials are remarkable for their hardness and the ease with which they acquire a brilliant polish, but the greatest care must be taken in their manufacture, in order to prevent their becoming black or being covered with greenish spots. Starting from the conviction that these imperfections are due to oxidation during the process of manufacture, Messrs. E. Schrader and O. Dumeke devised the following apparatus: A cylindrical boiler, made of iron and copper, is put into masonry in an inclined position. The resinous materials are melted by means of superheated steam, which expels the air from the vessel, thus avoiding the danger of oxidation. When melted the material is forced by steam pressure out of the boiler through a tube in its lower part. The temperature is kept well in hand, so that there is no danger of decomposition. The top of the apparatus is provided with a manhole, a safety-valve, a pipe to carry off the volatile portions of the resin, and a stirrer passes through it. The clear material is conducted in pipes, which have vents for the escape of gases. The value of the apparatus consists in the security it offers for melting large quantities with certainty of success, and in the protection it affords to the workmen.

DETERMINATION OF SILVER IN GALENA.—The Volhard principle of the direct determination of silver in galena is as follows: From 2 to 5 grammes of the galena, according to its supposed richness in silver, are very finely ground and intimately mixed in a porcelain mortar with from 3 to 4 times its weight of a flux composed of equal parts of soda and saltpetre, placed in a porcelain crucible, covered, and heated over a burner to thorough fusion, when the mixture is well stirred with a glass rod. It is then let cool, and placed in an evaporating dish partly filled with water, in which the melted matter is softened, dissolved out of the crucible into the dish, which is then heated, and the watery solution is filtered into a flask. The residue on the filter, after being well washed, is rinsed back into the dish, very dilute nitric acid is added, and the whole evaporated to dryness. The dry residue is taken up in water acidulated with nitric acid, heated, and filtered into the same flask in which is the aqueous solution. The residue is washed with hot water, the filtrate is allowed to cool in the flask, ferric sulphate or iron alum is added, and the liquid is titrated. —C. A. M. Balling, in *Oest. Zeitschrift Berg. u. Hutten.*

PAINTING FLOWERS UPON MIRRORS.—An art lately revived in Rome is the old Venetian art of painting upon mirrors. Birds and butterflies are also often added, and the effect of the glass underneath, especially when this is thick and beveled, is to make them appear as if suspended in the air. The design must be traced from natural flowers with a lithographic pencil, and painted in oils with peculiar care; for nothing can be more unlovely when badly done with muddy ill-assorted colors. These mirrors are usually framed in carved ebony or ebonized frames in the cinque cento style, another fashion recently revived.

ZINC-PLATE FILM.—Husnik's plan for causing a chromated gelatine film to adhere to a zinc plate is to coat the zinc plate with a solution of three grammes of chromic acid in one thousand grammes of water. When the acid has acted upon the zinc, wash off the solution, and first coat the plate with plain gelatine, and then with the chromated gelatine. Treated in this way, the film is said to adhere very firmly to the zinc; but it must be kept dry before being used, otherwise a chemical reaction is apt to set in, by which the printing surface would be spotted.

PRINTING LABELS ON BOTTLES.—The London *Chemist and Druggist* refers to a method of labeling bottles by a process invented in Germany. The labels are printed on the bottles themselves by a simple operation, neither paper nor uncilage being required. There is no trimming or moistening of labels. The bottles are placed in the hands of a printer, who delivers them at the rate of 1,000 a day, labeled in a neat and finished style. The process is an actual printing, not an stoking or a sand-blast. The labels can be scraped off with a knife, through they are not affected by water. They are not so opaque as paper, and beautiful effects can be obtained by using a white ground on bottles filled with colored substances. Bottles can be labeled when full as easily as when empty, and the address of the sender can be attached by this process to proprietary articles. Labeled by this method is said to cost no more than by that now in use.

NEW APPLICATION OF PAPER.—In the Portsmouth dry-dock a vessel was hauled up for repairs, and it was observed that a portion of the hull, to which a piece of paper adhered, was free from grass and mussels. Experiments were instituted, which led to an application for a patent for paper sheathing. As it can easily be impregnated with poison, it will probably act as a protection against borers as well as against ordinary fouling. —*Fortsehr. der Zeit.*

COLORING PENCILS.—L. von Faber makes pencils for writing upon glass, porcelain, metal, etc., as follows: Black—10 parts of lamp-black, 40 parts white wax, 10 parts tallow. White—40 parts white lead, 20 parts wax, 10 parts tallow. Blue—ten parts Berlin blue, 20 parts wax, 10 parts tallow. Dark blue—15 parts Berlin blue, 5 parts gum arabic, 10 parts tallow. Yellow—10 parts chrome yellow, 20 parts wax, 10 parts tallow. —*Dingler's Journal.*

IMPROVED VULCANIZED RUBBER.—C. Schwanitz, Jr., of Berlin, uses glycerine in the preparation of vulcanized rubber, in order to secure it from injury by fats and oils. He also passes the finished mass between warmed rolls, in a glycerine bath, in which it is exposed to steam, under a pressure of two or more atmospheres.

GOOD HEALTH.

Work and Worry.

"Studying too hard," "over-worked," are charged with many deaths, but not wisely. Trouble kills. It is a very rare thing for a man to think himself to death, unless connected with something more or less distressing. Study is a blise to the student—he had rather study than eat; the sound of the dinner bell is always unwelcome. The greatest students in moral philosophy, and divinity, and physics (not physic), have lived long, and worked efficiently to fourscore and beyond. Thought is to the brain what exercise is to the physical constitution; it keeps the channels of life clear, the blood-vessels unobstructed, and the vital fluid courses along them, distributing newness of life and vigor of action to the latest hour of existence, while the want of thought brings stagnation to the circulation, and causes man to drift and sleep in old age—dead as to everything except to eating, and dozing, and hovering over the fire. Men may study ever so hard, and after 50 may study with comfort and advantage for 5, 10 and 15 hours, day after day; and, if the studies are pleasurable, they promote the general well-being of the system, both physical and mental, if only abundant sleep is had, with a regular supply of simple and nourishing food, sitting down to meals in pleasant moods, and allowing a good half-hour before study is resumed. Many of our literary men die prematurely, not from over-study, but from depressing mental states and irregular or excessive eating and drinking.

It is haste, rather than steady, continuous labor of body or mind, which hurries multitudes to their graves scores of years before their time. With all haste there is impatience, solicitude, worry. The fastest trains, the fleetest steamers, the first trotters, everywhere command premiums. To save time, "night boats" are patronized, breakfast is bolted, the morning paper read on the cars, and everything is done under high pressure. But, just as certainly as a hank balance, rapidly drawn upon, melts away before it was expected, so does this reserve of vital stamina disappear—is used up—and the man dies in his prime, at the very moment, often, when he had just got into a position where he could afford to enjoy himself. —*Hall's Journal of Health.*

TO PREVENT BOILS.—A very simple remedy is made known by Dr. Sieven, in a St. Petersburg journal, for preventing the development of boils. He states that if the skin be superficially scraped with a small knife, so that a drop or two of blood may be pressed through the epidermis as soon as the peculiar stinging or pricking sensation and slight induration announce the commencement of the boil, it will not be further developed.

Suggestions for the Sick-Room.

In preparing a meal for any one whose appetite is delicate, it should be made to look as tempting as possible. The tray should be covered with the whitest napkin, and the silver, glass, and china should shine with cleanliness. There should not be too great a variety of viands, and but a very small portion of each one. Nothing more quickly disgusts a feeble appetite than a large quantity of food presented at one time.

The patient should never be consulted beforehand as to what he will eat or what he will drink. If he asks for anything, give it to him, with the doctor's permission; otherwise, prepare something he is known to like and offer it without previous comment. One of the chief offices of a good nurse is to think for her patient. He slightest want should be anticipated and gratified before he has had time to express it. Quick observation will enable her to detect the first symptom of worry and excitement and to remove the cause. An invalid should never be teased with the exertion of making a decision. Whether the room is too hot or too cold; whether chicken broth, beef tea, or gruel is best for his luncheon, and all similar matters, are questions which should be decided without appealing to him.

Household troubles should be kept as far as possible from the sick-room. Squabbles of children or servants never should find an echo there.

In the event of some calamity occurring, of which it is absolutely necessary the sufferer should be informed, the ill news should be broken as gently as possible, and every soothing device employed to help him to bear the shock.

Above all, an invalid, or even a person apparently convalescent, should be saved from his friends. One garrulous acquaintance admitted for half an hour will undo the good done by a week of tender nursing. Whoever is the responsible person in charge should know how much her patient can bear; she should keep a careful watch on visitors of whose discretion she is not certain, and the moment she perceives it to be necessary politely but firmly dismiss them.

She must carry out implicitly the doctor's directions, particularly those regarding medicine and diet. Strict obedience to his orders, a faithful, diligent, painstaking following of his instructions will insure to the sufferer the best results from his skill, and bring order, method and regularity into domestic nursing. —*Scribner for September.*

FUNGUS IN MAN.—The human ear is sometimes attacked by a disease which shows itself in the form of a running sore; in many cases the tympanum is destroyed and hearing lost before the nature of the malady is discovered. The disease is due to the growth of a microscopic plant or fungus of the *Aspergillus* family. It especially thrives when, from any cause, the secretion of the wax in the ear is stopped or hindered. The microscope is a valuable assistant in the discovery of this fungus. Consumption, the most disastrous malady that afflicts humanity, is now said to be caused by a yeast plant that flourishes in the blood. The presence of this fungus in the blood is readily shown by the microscope, and now forms the subject of careful study among physicians. Ephraim Cutter, M. D., of Boston, Mass., has devoted much labor to this subject, and, we understand, has recently produced micro-photographs of the fungus with Tolles' remarkable one-seventy-fifth objective. We believe that Dr. James H. Salisbury, of Cleveland, Ohio, was among the earliest to detect and describe this curious yeast plant of the blood. —*Scientific American.*

ERYSIPELAS FROM SEWER-GAS.—It has been proved beyond a doubt by observations in England that erysipelas is often caused by the entrance of sewer-gas into houses and hospitals. The London *Sanitary Record* remarks that "there is now no more doubt that erysipelas is originated by sewer-gas than that typhoid fever is due more often than not to impure water." Several cases at Lincoln and Manchester are cited. At the latter city many cases of erysipelas and pyæmia were traced to the hospital sewer-gas. The *Record* condemns lead soil pipes, and says: "We have known cases of the escape of sewer-gas through a 'rat-eaten' (or gas-corroded, which is far more common), lead pipe, in spite of good arrangements for its ventilation. Let the pipes be of iron, and well ventilated, and all mischief from this source may really be defied."

ARSENIC IN WATER COLORS.—According to the *Chemiker-Zeitung*, M. Fleck, in searching into the causes of the death of a young engineer, found in the corpse remarkable quantities of arsenic, the origin of which he attributed to the water colors which the deceased had been in the habit of using; for, on an analysis, he found that a specimen of sepia contained 2.08% of arsenious acid, one of terra di Sienna 3.14%, and one of red brown 3.15%. The deceased engineer having been in the habit of drawing his brush, charged with the color, through his lips, it is not impossible that the arsenical colors were absorbed by degrees in the saliva.

NEWS IN BRIEF on page 204 and other pages.

Business Announcements.

Assessment Notices—Pacific Land & Trust Co.

The Week.

News from the various mining localities of the State indicate a strong revival of the mining business, evidenced by renewed activity in the development and working of old and new mines. The quartz mines are busy turning out good paying ore as fast, if not faster, than it can be handled. Active preparations are being made to open up placers and hydraulic mines. The Big Bar, in Butte county, has developed a rich-paying streak of gravel along the bedrock, which will be mined hereafter by drifting, instead of the hydraulic process. Mono county is still developing its rich mines, and extra exertions appear to be made to make the yield second to none, which the appearances seem to justify. Nevada county is developing rich quartz finds, and recent developments at Little Grass Valley have disclosed a promising gravel mine, which is to be worked on a large scale.

San Bernardino nor Los Angeles county do not seem willing to be left behind in the golden harvest, and are both finding silver with some traces of gold. The Sitka quartz mines at Alaska are assuming good paying qualities, and new ledges are being discovered every day according to reports. Active preparations are made in Oregon, for the full working of mines, which, heretofore, have been only slightly worked at intervals.

Carbonates carrying very rich assays of silver are continually being unearthed in Colorado, and the already developed mines are exceeding the expectations of their owners. In Grant county, New Mexico, some rich ledges have been discovered in the mountains to the north and east of the Mimbrres. New and rich discoveries of ruby and native silver have been made in Alturas, Idaho. Every where in the Rocky mountain region, from Alaska to Mexico the prospector has been encouraged and rewarded by unlooked-for strikes of precious minerals.

The Argentine Government has refused an American offer of \$6,000,000 for the Tucuman Railway.

Defects in U. S. Mining Laws.

Questions Submitted by the Public Land Commission.

By an Act of Congress, approved March 9th, 1879, a "Public Land Commission" was organized, the duty of which is to report to Congress within one year of that date: *First*, a codification of the present laws relating to the survey and disposition of the public domain; *Second*, a system and standard of classification of public lands, as arable, irrigable, timber, pasturage, swamp, coal, mineral lands, and such other classes as may be deemed proper, having a due regard to humidity of climate, supply of water for irrigation, and other physical characteristics; *Third*, a system of land parcelling, surveys adapted to the economic uses of the several classes of land; and *Fourth*, such recommendations as they may deem wise in relation to the best method of disposing of the public lands of the western portion of the United States to actual settlers.

The Commission met in this city this week at the Surveyor-General's office, all present except Major Thos. Donaldson, of the Smithsonian Institute. The other members are: Gen. J. A. Williamson, Commissioner of the General Land Office at Washington, and Chairman of the Commission; Clarence King, Chief of the Geological Survey; Major T. W. Powell, of the same Survey; Alexander T. Brittan, President of the Land Attorney's Association of Washington.

Nevada, Utah and Colorado, have already been visited by the Commissioners, who after finishing their work in California will go to Oregon, Washington Territory and Arizona.

The Commissioners divided up as follows for making a tour of inspection among California Land Offices: Major Powell, assisted by Captain Dutton, and accompanied by a stenographer will go through the San Joaquin valley as far south as Los Angeles. General Williamson and Mr. Brittan will journey north to Shasta, while Clarence King will inspect the quicksilver and gold mines located in the section of country south of San Jose. Returning, the Commissioners will meet in the Surveyor-General's office on the 4th of October, and report the result of their observations.

Aside from the general questions and those relating to agriculture, timber resources, etc., the following questions propounded by the Commissioners will be of interest to the mining community, and all persons interested are asked to answer them by letter directed to the Public Land Commission, P. O. Box 555, Washington, D. C.:

Lode Claims.

1. What experience have you had, and where, and in what capacity, in the business of mining, mine surveying, and mine litigation.

2. What defects, if any, in the United States laws, their operation and administration as applied to lode claims; do you know, either from your own experience or from observation?

3. What is your opinion as to the present official practice of filing surveys of lode claims which overlap on the surface? State instances and inferences in full.

4. What do you understand to be the top or apex of a vein or lode? Can or cannot the top or apex, the course and angle or direction of the dip always be determined in the early workings of the veins or lodes?

5. If no, are the intended rights of a discoverer properly defined and protected by the locating of a claim under the existing laws, of which the foregoing terms are essential parts?

6. Within your experience and knowledge, has or has not litigation and injustice grown out of the impossibility of determining the above points?

7. Have you known of two seams, parallel or otherwise, of the same outcrop, being located by different parties and giving rise to contest?

8. If yes, in such a contest have you known of the original locator being cut off in depth by the later locator?

9. Are or are not the outcrops of lodes often wider than the legal width of claims, whether as defined by the United States, State, Territorial, or local district regulation?

10. Do or do not outcrops of narrow lodes sometimes so deviate from a straight line as to pass beyond the side lines of claims?

11. Does the practice under the law of permitting lode locations of alleged lodes, on non-mineral ground, work to the advantage or disadvantage of the discoverers of true lodes?

12. If A, on the outcrop of a true lode, makes a location and B locates a parallel claim outside the side lines of A's tract but over the dip of A's lode—B's subsequent location being on an alleged lode but really on barren ground—can B, who has discovered nothing, cloud the title of A, the discoverer of a true lode, and put him to the cost and inconvenience of an expensive litigation? State instances and give particulars of the same.

13. Are or are not a large majority of the discoverers of rich veins, or their assigns, often burdened with costly litigation to defend their rights from subsequent locators in their immediate neighborhood? and in such cases is or is not the legal attack most often directed to the portion of the dip of the lode which has passed beyond the exterior lines of the surface tract?

14. In view of the known variety and complexity of mineral deposits in rock in place, is it, or is it not, in your judgment, possible to retain in the United States mineral laws a provision by which locators can follow the dip of their claims outside their side lines without provoking litigation?

15. Have you ever taken part in organizing a local mining district? If so, state fully where it was done; by how many parties, and whether necessarily actual miners or citizens? What officers were elected, and their duties? What books of record provided, and their object?

16. State generally the mode of originally taking up and locating a mineral claim under mining customs and the effect of a record of such location.

17. Is that record capable of subsequent amendment? and if so, how?

18. Within your knowledge, have mining titles been disturbed, or litigated, through fraudulent manipulation or destruction of these records? If so, what security is there against such frauds?

19. Calling your attention to the fact that a copy of the certificate of location, as certified by the local mining recorder, is the sole basis of the paper title for a mining claim, under existing law, and that compliance with the varying customs of innumerable mining districts constitutes the preliminary acts upon such claims—state, whether in your opinion, all mining district laws, customs and records could advantageously be abolished as to future locations, and the initiation of record title be placed exclusively with the United States land officers?

20. Calling your attention to the fact that under present laws an adverse claim, in proper form and seasonably filed, suspends the administration of the mineral laws by the United States land officers, and transfers the jurisdiction to the courts of law, both State and United States—please state whether, in your opinion, the adjustment of controversies concerning mineral lands prior to issue of patent should not be left absolutely to the United States land officers, in the same manner as contests under all other land laws?

21. If you consider it desirable to retain the leading features of the United States mining laws, what amendments, if any, would you suggest to remedy any defects which your experience or observation has detected? If, on the contrary, you believe that the practice of following the dip beyond the side line of a claim is incompatible with satisfactory administration, what method of location would you suggest?

22. Ought there not to be a limitation as to a possessory title under the mineral laws? and should not locators be compelled, on penalty of forfeiture, to acquire the title by purchase from the Government within some reasonable time? If so, what would be your idea of the time?

Placer Claims.

1. What proportion of the lands in your section is mineral, and what is the nature of the mineral deposits?

2. Are you familiar with the practical operations of the United States mining laws? If so, state how and to what extent.

3. From your personal experience, please state the time and expense of procuring a mineral title, whether possessory or by patent—both with and without contest.

4. State your knowledge of the experience of other parties upon the same points.

5. Within your practical experience, are the existing mining laws as to placer claims defective or otherwise?

6. If defective, state in what particulars; having especial reference to the facts of original location under local customs or laws; the shape and size of such claims; their occupancy and development; the opportunities for consolidating two or more claims in one person by purchase; what evidence of the chain of title is required; what use is made of such claims other than actual working, if any; and what is the general character of the litigation relative to these placer claims?

7. Within your knowledge, are titles obtained under the placer law for non-mineral lands, and if so, state instances.

8. Within your knowledge, has the placer law been used to obtain titles to lode claims? If so, state instances.

9. Do you know valuable placer lands which are unworked because the outlets are controlled by claimants under other than mineral titles? If so, state instances.

MEXICAN DEBT.—It appears from a statement in the *Trait d'Union* that the total debt of Mexico is only \$59,999,300, being \$6.20 per capita of the population, the lowest of all the American governments except Columbia, which is \$5.33. A writer in *Las Dos Republicas* finds consolation in this fact, and finds that the United States has a debt of \$63 per capita; hence we are ten times worse off than Mexico. The brilliant future of Mexico would be assured if it had peace and order, etc. But when her people will cease their needless strife no man can foretell. The small debt of Mexico is probably kept small by inability to borrow. There is hardly an individual in the United States that could not pay his per capita share of the national debt, while it would require a multitude to pay the \$6.20 allotted to each. Capacity and ability is what makes the difference.

Gold bars and eagles to the value of £100,000 will be shipped to the United States Saturday from England.

Alloys of Silver with Embrittling Metals.

The result of a series of experiments made at the United States Mint, in Philadelphia, by Alexander E. Outerbridge, Jr., has lately been published in the *Journal of the Franklin Institute*. The experiments were undertaken principally to save loss of metal in the "toughening" process, and with a broader view of furnishing reliable data as to the relatively injurious effects upon refined silver of small but known percentages of such base metals as were supposed to impair its good qualities. It is a fact well known to metallurgists that the presence of certain base metals in refined gold and silver, even in small percentages, exercises such an injurious effect in regard to ductility, hardness, etc., as to render the metal totally unfit for coin or the industrial arts, thereby necessitating the removal of these impurities by oxidizing fluxes or other equivalent means.

It is also well known that during the process of removing these impurities ("toughening") an inevitable, though variable, loss occurs, which is traced to three causes:

1. To the formation of volatile compounds of gold or silver with the base metals.

2. To the violent action on the surface of the metal during the decomposition of the oxidizing agent, thereby causing minute particles of the molten metal to be sprayed from the surface.

3. To the upward current of air and flame sweeping over the surface of the molten metal in the pot drawing into the flue the vaporized metal and the fine spray.

These vapors are carried out of the chimney where they partially fall, in a sort of fine rain, upon the roof of the Mint and adjoining buildings, and a larger portion is carried into free space and lost. Unsuccessful attempts have been made to recover this metal thus dissipated by means of shelves and other devices arranged in the flue, but their use tended to impair the draught in the wind furnace.

It was to overcome these difficulties that Mr. Outerbridge devised an apparatus to prevent the metallic vapors and gases arising from the melting pot from escaping into the flue at all by drawing them off into a suitable condensing chamber. The trial tests were commenced and continued from time to time until they were suspended owing to the unprecedented increase in the regular work, consequent upon the passage of the Bland Silver bill. So far, as completed, however, the tests include the preparation and subsequent examination, analysis and refining of alloys of silver with arsenic, antimony, bismuth and lead.

A brief recapitulation of the results obtained in this work, which are regarded only as preliminary and therefore capable of possible modification on more extended investigation, are as follows:

It was ascertained that the arsenical silver alloy, contrary to the general expectation, was the least volatilizing in silver in comparison with more refractory metals, and that the alloy might contain one per cent. of arsenic (silver 990, arsenic 10) without materially injuring the ductility; but if carried to 2½%, the mixture was quite brittle.

The antimonial-silver alloy caused a very much greater loss of silver, and yet its brittling effect was much less than had been anticipated.

Bismuth was the most brittle, and in this experiment proved by far the most difficult to remove by fluxes that operated effectively upon the two former.

Lead caused a greater loss than any of the former with the exception of antimony. The brittleness of those was crystalline, of this rather crumbly or amorphous, yet three parts in a thousand did not spoil the ductility.

It is hoped that the trials may lead the way to future investigations, which are much needed to afford a complete elucidation of the difficulties that beset the manipulator in the precious metals, whether in the preparation of coin metal, ornamental ware or gold leaf, in the want of ductility of the alloys.

In a letter concerning the report of these experiments, Mr. Wm. E. DuBois, chief assayer of the Mint, says: "I took a particular interest in this investigation for two reasons: First, I was sure that we knew too little practically about the effect of a small presence of such metals as arsenic, lead, etc. That is, we depended too much upon supposition, as to the extent or the degree in which they were injurious to the precious metals for coining purposes. Arsenic, antimony, bismuth and lead are the chief enemies that trouble the camp of the silver miner and refiner. Nor are they less dreaded at the Mint, since a small proportion of either will make our gold or silver refractory, brittle, crystalline or crumbly. We must have ductile metal to work with. Hence these experiments have for us a two-fold interest, as hitherto there have been no trials that we know of, at home or abroad, on any considerable scale, or in proper bulk."

About 1,000 ounces of silver was adopted as the normal weight of refined metal to each experimental melt.

ZULU MINING DISTRICT.—This is the name of a new mining camp lately discovered in Provo, Utah. The quartz from the Zulu ledge assays, in gold and silver, \$1,260.50 per ton. Many claims are staked off and being surveyed, a new town is laid out, and expectations run high.

Silver Mines of Batopilas, Mexico.

Around the small town of Batopilas, in the southwestern corner of the State of Chihuahua, Mexico, is a group of silver-bearing veins, which are among the most interesting deposits of the precious metals known. The town itself is a dilapidated Mexican mountain town, consisting principally of adobe houses very much out of repair, which, with the ruins visible at every step, would be unlikely to strike the observer as being the center of great wealth and productiveness at the time of Humboldt's visit; yet there is ample evidence of its being entitled to a prominent place on the list of rich mineral centers.

Mr. H. A. Stearns, of Batopilas, now on a visit to San Francisco, has favored us with some interesting information concerning this district, which we lay before our readers. The town is about 400 miles from the coast, and may be reached from either Guaymas or Mazatlan, by way of Alamos or El Fuerte, which places are its base of supplies, being 208 miles from the former and 130 from the latter. From the coast to these towns the roads are good and practicable for wagons, though that means of conveyance is little used. After passing Alamos and El Fuerte, the western base of the Sierra Madre is soon reached, and the roads dwindle down to mule trails, steep and rugged, but over which all machinery must find its way to the interior.

Batopilas is situated in the very heart of the Sierra Madre, in a deep "barranca," or gorge, through which flows the river of the same name, joining the Fuerte river and thence to the Pacific ocean. High mountains surround the town on all sides, rising from the banks of the river to an elevation varying from 2,000 to 4,000 feet above the bed of the stream, barely leaving room for the town sites. This old town was destroyed some years ago by one of the freshets peculiar to the river during the rainy season, from July to October. From the loftier mountains on the northwestern side run a number of deep ravines, which enter the river nearly at right angles, giving shape to the lofty mountain spurs known as the "Hill of Animes," "Hill of Escritorio," etc. The "Animes" has a general altitude of about 3,000 feet, the descent to the "Arroyo Grande," or "Arroyo Pastrana," on its southern side, being abrupt, the hill falling off rapidly as it approaches the river. The "Escritorio" is much lower, the northeastern crest being about 2,000 feet. The mountains in the immediate vicinity of the town are covered with a dense growth of small trees, shrubs and cacti, which furnish an abundant supply of firewood. The mountain west of town are covered with a scattered growth of oak trees and abundant grass, the loftiest summits producing a variety of pine sufficient for building purposes. The mining timbers are cut by the Indians in the mountains, peeled and dragged down to the mines. The climate is delightful, and at all times there is sufficient water in the river to supply the reduction works located on its course. The average fall of the river is about 40 feet to the mile.

The history and production of Batopilas is but little known, and consists mainly of traditions and a few official documents, together with the evidences of ancient workings of the mines. Reports relegate the workings of the mine to the last century, and the unearthing of the lower works of the Pastrana mine last summer confirmed an official report dated in 1792. Various causes rendered cessation of work in the mines necessary, the unsettled condition of the country being the principal one. The mines remained idle for many years, in fact, until 1859, when Don Jorge Le Brun commenced an adit to drain Pastrana, before finishing which a wealthy New York company purchased the entire interests on the hill of San Antonio, including the famous Carmen and San Antonio mines. This company prosecuted a deep drain tunnel commenced about 10 years previous by a Mexican. This tunnel cuts the veins in the hill of San Antonio at a depth of about 600 feet and is largely remunerative. Their success stimulated others and the once famous district of Batopilas has entered another era of prosperity.

The geological structure of the district is simple, the variety of rocks being small, but their relations are so complicated as to be difficult of solution. The formation consists of granite, greenstone, and highly metamorphosed slate, the whole capped by an immense floor of white, compact porphyry, known as "Tierra blanca" (white earth). It has a tendency to columnar structures, and gives the main features to the landscape, converting the summits of all the higher mountains into a level table land, with precipitous mural faces. From the summits west of town, looking in the direction of Chihuahua, up the valley of the Rio de Batopilas, the country resolves itself into a vast plateau, cut up by deep canyons, the escarpment of the Tierra Blanca being frequently several hundred feet in height. In the neighborhood of town, greenstone and slates predominate, both so intricately mixed as to make an exact definition of their boundaries a difficult matter; the location of these and the granite being frequently detected by their weathering, the granite to coarse sand, the greenstone to a reddish gravelly soil, and the slates to small, angular fragments.

The silver-bearing veins are included within an area of about two miles and three-quarters in length, on a line northeast and southwest from

the San Antonio mine to the Gnadalupe, at the base of the "Tierra blanca" bluffs west of town, with a breadth from northwest to southeast of a little over two miles, the most valuable portion, however, not having a breadth of over one mile. The veins have a strike varying between north 40° west and north 40° east, with varying dip, cutting the formation nearly at right angles, passing from one rock to the other, but being pinched, broken and barren where they enter the granite. In the slates and greenstone they vary from a few inches to several feet in width; the same vein, when barren, being barely traceable, but, when productive, widening out to 2, 3, or even 10 and 12 feet, between the walls. The veins, though small, possess a remarkable permanence and regularity. Not unfrequently small threads, only 2 or 3 inches in thickness, will pay handsomely for exploration. With the exception of a few unimportant veins, which have a gangue of quartz and produce ore of copper, carrying but a small percentage of silver, the gangue is calc-spar. The silver occurring chiefly in the native form, associates with small quantities of chloride of silver near the surface, and silver glance and light red ruby silver in depth. The less valuable minerals are galena, arsenical iron pyrites, and a yellow zincblende, the latter being a constant companion of the silver, and, wherever found, a sure indication of the near presence of that metal. Some veins yield a much larger percentage of the sulphureted ores than others, but in all they form but an insignificant proportion of the value of the ore, which carries chiefly native silver.

Batopilas has yielded some very large masses of native silver, and the ore is frequently so full of metal, that in drilling the blast holes, they become lined with a sheet of silver, blowing off like a cannon instead of throwing down the ore.

The river, the arroyos of Carmen, Chiquito, Pastrana, Dolores and San Antonio de los Tachos, naturally divide the district into six subdivisions. On the east of the river is the hill of San Antonio, on its south the hill of Tajos. On the west of the river lies the hill of Animes, being in reality the extension of the hill of San Antonio cut through by the river. South of the arroyo of Pastrana comes the Escritorio hill; south of the arroyo of Dolores is the San Antonio de los Tachos group, and still further to the southwest the hill of Descubridora.

The majority of the mines at Batopilas, although very ancient, had apparently been worked at the surface only; in some few the workings had penetrated to the vein a few hundred feet, but were abandoned. The developments that have been made by means of the continuation of Mendoza's tunnel, before alluded to, have indicated a richness which the ancient miners, satisfied with mere surface digging, could not realize. The veins cut by this tunnel are very numerous, in fact numbering 17 in all, the principal being Las Tierras, Dolores, La Rona, Geral, Rata, Mesquite, La Sastre and Juan Vaca, varying in width from one-half to three varas. All of these veins show silver in considerable quantities, some of them showing fine bodies of calc-spar well charged with fine, crystallized native silver, carrying some silver glance. The Geral in particular, though but slightly opened, paid the expenses of the entire concern. On the Juan Vaca vein the ore channel crosses the main tunnel diagonally. Drifting was commenced to the north, and after penetrating five varas, a vein of heavy metal about 18 inches thick was found occupying the whole height of the breast. Explorations during the past summer showed a stratum nine feet thick of first-class ore, some of which yielded about \$6,000 per ton. The hill of Antonio and of Animes have so far proved to be the richest. The ancient surface workings having yielded immense amounts, subsequent late developments disclose the fact that the veins are richer below than at the surface. This is being demonstrated by the Antonio tunnel which is now working some 600 feet below the surface, and encountering silver ore so rich as to be difficult to blast, on account of its metallic nature. In the other districts the veins have produced large quantities of rich ore, and still contain unexplored riches. Traces of ancient workings are found everywhere, which, as has been said, were either at the surface or penetrated but a comparatively short distance on the vein, only those being worked which yielded silver at the surface.

Mining in Batopilas is rude in the extreme. A shaft or "posa" is sunk to the depth of about 10 varas, if the bunch of silver continues downward. From the bottom a short drift is run on the vein; from this another shaft of 10 varas is put down, this plan being followed to the deepest workings, and is required by the mining laws as a protective measure. Poles, notched to serve as ladders, afford access from

one part of the mine to the other, or laid side by side across the shafts for bridges. Up these ladders the ore is carried on the backs of peons, in sacks or "srones," holding about 150 pounds each. The ore is so rich that constant stealing is going on, and miners are willing to work for low wages on account of the "pickings." The ore is thrown down by blasting, the holes being made with a very long pointed bar, which requires considerable room for working. A home-made powder, of poor quality, is used. In those mines controlled by Americans, the short bar and sledge and American powder have produced excellent results. Developments are slow for various reasons; the miners soon become rich and cease work. Fortunately, the Mexican laws give any one the right to work a mine if the owner ceases to work it for four consecutive months, recognizing no ownership except that of actual possession and active development of the property.

The reduction of the ore at Batopilas is easy. The facility with which the precious metals may be separated from the ore forms one of its chief attractions. The richer ores are easily reduced by fire, the poorer ones by amalgamation, and the river furnishes all the necessary motive power. Probably two-thirds of the silver produced is by smelting. The heavy silver is first pounded with a hammer until freed from vein matter, in which state it is passed to a smelting furnace in quantities of 50 pounds, realizing a loss of only 2% to 5%, on account of the fine powder which could not be separated by the hammer.

The other grades of ore, termed "Brosa" and "Chispeado," are pounded on large stones with smaller ones until the heaviest and most visible nails of silver are separated, together with the buttons of solid silver which accompany them. These, after being purified by washing from the grains and powder of the gangue, are passed to the smelting furnaces in quantities equal to the first class, and produce a result of 80% to 90% solid silver. The debris are ground to a coarse powder in arastras, with water, so as to allow the silver to settle to the bottom upon the stones and between the joints. When thoroughly done, the sand is withdrawn from the arastra and the stones scraped with iron scrapers made for the purpose.

These settlements are also smelted. The tailings, or remaining sands, are again run through the arastra and ground very fine. After which these are treated with quicksilver (in the patio) in "montons," or piles, of 900 lbs. The poorer ores are ground fine in arastras and treated with quicksilver (in the patio) in quantities of about 1,200 pounds.

Ores are never found in this district which contain only silver in combination with sulphur, arsenic, antimony, etc., with native silver, and out being accompanied by the latter always in excess.

After amalgamation of the sands or debris there must be included the final process of concentration, for the purpose of saving the unreduced sulphureted and some little amalgam. The residue thus obtained is smelted with a little lead and cupelled as often as the accumulation will justify it. The ore worked in this way realize probably 95% of their value.

The district is isolated and inconvenient of access for machinery, but, owing to the nature of the ore, machinery is neither applicable nor desirable to any considerable extent. The only improvement that might be introduced would be crushers to replace hand breaking, and better water wheels to economize the motive power. The reduction by fire of one ton of first-class ore, yielding from \$10,000 to \$15,000, does not exceed \$50 to \$60; by amalgamation, per ton, yielding \$100 to \$500, the cost is only \$16 to \$25, according to the loss of quicksilver. The loss, at present, is very great, and might be greatly lessened by concentration of the ore previous to working. The great difference between the specific gravity of the calc-spar and silver would render this one of the easiest metallurgical operations.

A GOOD APPOINTMENT.—Walter A. Skidmore, formerly assistant to the commissioner of mining statistics on this coast, has been elected by the Hydraulic Miners' Association to collect such data as may tend to elucidate the vexed questions now in issue between the farmers and the miners, and to otherwise aid in promoting the objects for which this association was formed. Through his acquaintance in the mines, and his knowledge of the mining laws, Mr. Skidmore brings to the discharge of his duties such a special fitness as ought to make his appointment to this position advantageous to his employers.

It is probable that the U. S. Land Commission will recommend the abolition of the land office in this district and the consolidation of all similar offices, placing them under control of the Department at Washington.

Steber's Ratchet Drill.

The peculiarity in this improved ratchet drill, which gives it superiority, consists principally in the parts being formed in telescopic sections, having motions one upon the other, for the purpose of giving it capacity to work in different situations, where either a long or short drill is required. On account of this adaptability in regard to length it is adapted to a much greater variety of work than any other ratchet drill now in use.

The working screws are all inside, and hence not liable to become battered as on common drills. The telescopic sleeves fit one upon the other, so that the screws cannot become bent or strained in any way, and remain perfectly accurate through long use.

These ratchet drills are manufactured with the greatest care, of fine Stubbs steel. The working screws are cut upon a lathe and every drill warranted to bore a perfectly true hole. The center and paul are tempered perfectly. To engineers, railroad men, machinists, boiler makers, and all other workers in hard metals, it will be found a great desideratum. It is furnished with or without an extension handle, and of any size, by Dunham, Carrigan & Co., of San Francisco.

Gas as Fuel in Metallurgical Operations.

Prof. Hunter of Philadelphia, referring, in the *American Manufacturer*, to the use of gas as fuel in metallurgical operations, upholds the use of hydrogen as fuel; but shows that under atmospheric pressure it is not more valuable than carbon, so far as its calorific intensity is concerned. He urges that the distinction between the intensity (high temperature) and calorific value of fuel should be maintained, the former being needed in metallurgical operations and the latter in the generation of steam.

From experiment, the calorific intensities of carbon and hydrogen, burning in air, are as follows:

Carbon..... 2720° C. = 4928° F.
Hydrogen..... 2725° C. = 4937° F.

From this it is seen that the values under atmospheric pressure, as regards their intensities (high temperature), which alone is available for metallurgical purposes, are about the same.

These calculated amounts are the actual calorific intensity, values of the fuel, but are slightly higher than obtained in practice, owing to radiation, conduction, absorption and dilution. I have supposed that there was no excess of air, but this is not the case in practice unless a reducing flame is required; but, at all events, should there be an excess of air, it will diminish the intensities by absorbing as much heat in one case as in the other.

But now put both under pressure, or in other words, burn a greater amount of gas in a given time and space, and the intensity will instantly increase. To get carbon for fuel in the gaseous state, we must first convert it into carbonic oxide, and in doing this we lose much of the calorific intensity of the carbon where we need it. In the case of hydrogen it is different. Now suppose we admit carbonic oxide under a given pressure, the calorific intensity would not be near as great as hydrogen under the same pressure, hence I prefer hydrogen as fuel in preference to carbonaceous fuel. In one of my improvements in metallurgical operations I admit hydrogen mixed with other gases, under pressure into the furnace, whereby I obtain increased effect.

Phosphorus in Coal.

The necessity of great care in the selection of proper ore, flux and fuel in the manufacture of pig iron for conversion into steel by the Bessemer and open-hearth processes, has directed the attention of Andrew S. McCreath, of Harrisburg, Pa., to the examination of the bituminous coal of Pennsylvania, who gives the result of his investigations in a late number of the *Journal of the Franklin Institute*. It is necessary that iron intended for conversion into steel should be very pure, and especially must it be comparatively free from phosphorus. Only such ore as are practically free from phosphorus can be used, and pure fuel is as much a necessity as pure ore, though hitherto iron men have paid comparatively little attention to this point.

Forty specimens were examined, the greatest number of which were selected from the Pittsburgh bed, because it is the principal coal-bed of southwestern Pennsylvania, and most of the mineral fuel which is mined along the Youghiogheny and Monongahela rivers, to be used in the coke ovens of the Connellsville region and in the blast furnaces and mills of Pittsburgh and its vicinity, and to be shipped to western and southern markets, comes from this bed. In 24 specimens tested from this bed, the amount of phosphorus varies from a mere trace to .1248%, equal to .2003% in the coke. Such a coke could not of course be used in the manufacture of Bessemer pig iron, and it is believed that in many cases unsatisfactory results have been obtained simply by the use of an impure fuel.

NEVADA and Colorado miners have purchased silver workings in the neighborhood of Thunder Bay, Me.

STEBER'S RATCHET DRILL.]

DEWEY & CO.

American & Foreign Patent Agents,

OFFICE, 202 SANSOME ST., N. E. COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 202 Sansome St., N. E. corner Pine, S. F.

Photo Relief Wood Engraving

The use of Photography in producing stereotype and electrotype plates for artistic and common printing, forms, comparatively, a new method, in which we are making continual improvements and executing different kinds of work, superior to any before issued. It also enables us to produce certain kinds of work at greatly reduced prices.

Designing and Wood Engraving of every variety in the best style of the art, continued as usual. All orders executed promptly and on the most reasonable terms. We guarantee satisfaction. For the credit of our own journals, our customers can rely upon first-class work of the styles desired.

SCIENTIFIC PRESS ENGRAVING CO.,

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men! SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

TUBBS & CO.,
611 and 613 Front Street, San Francisco

C. C. Bitner's Apparatus for Obtaining Metallic Copper from its Solutions.
Patented March 18th, 1879. Will precipitate with steam in three hours, requiring no machinery to run it. Cost of constructing apparatus, \$75. The old cylinder process takes four hours to precipitate and costs from \$1,200 to \$1,500 to construct, besides the machinery to run it. For right to use my Precipitator address O. O. BITNER, Spenceville, Nevada County, California.

Books for Miners and Millmen

KUTSEL'S ROASTING OF GOLD AND SILVER ORES, and the extraction of their respective metals without quicksilver. Illustrated, 142 pages, 1870. A valuable and carefully written work. Postpaid, \$2.50. Published and sold by Dewey & Co., S. F.

KUTSEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arseniurets, and gold and silver ores generally, with 120 lithographic diagrams, 1867. This work is unequaled by any other published embracing the subjects treated. Postpaid, \$7.50. Printed and sold by Dewey & Co., S. F.

PHILLIPS' EXPLORERS, MINERS AND METALLURGISTS COMPANION, comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy. 672 pages and 63 illustrations. A most valuable and comprehensive book of reference to prospectors and practical miners. Postpaid, \$10.50. Sold by Dewey & Co., S. F.

AARON'S TESTING AND WORKING SILVER ORES.—Illustrated, 114 pages, 1878. A useful and practical work, free from technicalities and extremely serviceable for miners' use. Postpaid, \$2. Published and sold by Dewey & Co., S. F.

COPP'S HANDBOOK OF MINING LAWS.—Containing the U. S. Mining Laws, Digest of Decisions, Forms, etc., 1877. Pocket size, and very handy and convenient for miners. Postpaid, \$1.00. Sold by Dewey & Co., S. F.

PALACE RESTAURANT
218 Sansome St.
This elegant and spacious S. F. Restaurant has been re-opened with superior bill of fare daily.
Good Living at Reduced Prices
ly, and is now the best and most popular dining saloon on this Coast.

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office.

PHOSPHATE SOAP

THE BEST soap for toilet use ever manufactured. BEST because it contains all the excellencies of the most expensive foreign or American soaps without their defects. BEST because it combines strength with delicacy in such a way that its strong detergent qualities do not injure the skin. BEST because it is the result of years of study and experiment in the soap manufacturing business, assisted by modern chemical discoveries. BEST because it contains ingredients beneficial to the skin, which unite chemically with the soap in such a manner as to increase its saponaceous qualities. Every chemist familiar with soap manufacture knows that some ingredients which are in themselves beneficial to the skin cannot be saponified; some are partially neutralized, while others injure the quality of the soap. There are soaps in the market which are to some extent beneficial to the skin, but they are inferior articles for toilet use. PHOSPHATE SOAP is the ONLY article offered to the public which combines all the best elements of toilet soap with medical ingredients beneficial to the skin.

If your wife is in the habit of using cosmetics of any kind, advise her to give up the pernicious practice, as the most harmless face powders obstruct the pores of the skin and sooner or later injure the complexion, while PHOSPHATE SOAP removes all impurities and assists nature in developing a natural, healthy and beautiful skin.

It is an old proverb that an ounce of preventive is better than a pound of cure. Twenty-five cents invested in a cake of PHOSPHATE SOAP will save hundreds of dollars in doctors' bills. It acts as a constant disinfectant, preventing Salt Rheum and other skin diseases.

If your wife will persist in the use of cosmetics, buy her a cake of PHOSPHATE SOAP and tell her to use it every night before retiring. In that way much of the harm will be avoided, as the skin will thereby be able to retain much of its natural vigor and beauty.

No salve or ointment can heal a wound or sore of any kind. Every educated physician will tell you that nature alone can do this. PHOSPHATE SOAP, by its cleansing, soothing and purifying qualities, gives nature a chance to act freely.

Natural beauty surpasses anything which can be imparted by artificial means. PHOSPHATE SOAP gives health to the skin simply by removing impurities and eradicating the poisons which give rise to skin diseases.

Not only for daily use on the face and hands, but for bathing the entire body, there is nothing equal to PHOSPHATE SOAP. It is a thorough disinfectant and removes offensive odors of every kind.

Ladies who have injured the skin by the constant use of cosmetics may do much to restore their faces to that beauty which nature alone can give by constantly using PHOSPHATE SOAP.

For all diseases of the skin use PHOSPHATE SOAP. There is nothing like it for removing impurities and giving the skin a healthy and natural vigor.

Cheap toilet soaps manufactured from rancid and refuse grease injure the skin and are really more expensive than PHOSPHATE SOAP, which retails for 25 cents per cake.

Thousands of articles are palmed off on the public which have no genuine merit, but PHOSPHATE SOAP is the result of modern discoveries of celebrated chemists.

PHOSPHATE SOAP costs no more than other good toilet soaps, while its medicinal qualities make it worth ten times its price to every man, woman and child.

If you want a nice article of Toilet Soap and something that is beneficial to the skin, buy PHOSPHATE SOAP.

Metallurgy and Ores.**Nevada Metallurgical Works,**No. 23 STEVENSON STREET.

Coats of Arms, Creets, Monograms and Masonic Inscriptions Carefully Engraved.

CAUTION—To Section Chimney Builders.

All chimneys on which joint hands with cement, or its equivalent, are used to make the joint smoke and fire-proof with rods, clamps, or their substitutes, to brace the chimneys to the buildings, are INFRINGEMENTS on my patents. My patents for sectional chimneys have been sustained in every instance.

J. BROWELL, Pioneer Chimney Builder,
442 Jackson St., S. F., and 1200 Broadway, Oakland**Mining Books.**

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

**MINERS' HORSE-POWER.**

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

— PATENT —

LIFE-SAVING RESPIRATOR**Prevents Lead Poisoning and Salivation.**

INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Mines, Guano Works, White Lead Corroding, Feeding Threshing-Machines and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price \$3 each, or \$30 per dozen. Sent post-paid to any address upon receipt of price.

[CONTINUED FROM PAGE 197.]

The south drift on the 2760 level is in 110 ft., and cutting porphyry. Work elsewhere going on without change.

BEST & BELCHER.—The work of sinking the Joint Con. Virginia winz below the 1000 level will be resumed tomorrow. This winz is to be pushed to the 2150 level, and there will connect with the drift south from the Con. Virginia.

JULIA CON.—Excellent progress has been made during the past week in freeing the mine from the accumulation of water in it. It is hoped that the 2000 level will be dry by the last of the week. The new set of boilers is in place, and the masons are at work laying the containing brick.

MOUNT ROSE DISTRICT.

RATTLER.—Reporter: The Rattler mine is proving to be one of the richest prospects in Mount Rose district. There are now four men at work on the mine, who are taking out a ton of ore each, every 24 hours. The ore vein is from 14 to 18 inches wide, and we are informed is improving as work progresses. The ore now being extracted works \$150 per ton in silver.

LANDER CO.—Battle Mountain Messenger, Sept. 20: At Galena the Avalanche Veritas mine shows, along the line of tunnel, good ore for \$20 ft. A body of ore has been discovered in the Battle mine, which was passed over by experts. Three men are extracting \$100 in ore per day. Assays \$905 per ton.

WHITE PINE DISTRICT.

IREMS.—Eureka Sentinel: The main workings of the Jennie A. have attained a depth of 550 ft. At the bottom the ledge is found to be larger and softer. The vein runs from two ft to 40 ft in width. The ore is yellow and black carbonate, and will average about \$80 per ton. They have in sight ready for stoping not less than 10,000 tons. The experimental furnace will be completed and started up the present week. There is a large amount of ore on the dump and 150 cords of wood at the mine. The mine is located on the old Eberhardt mine, yielding some very rich ore. The Aurora tunnel is in between 4,000 and 5,000 ft. A number of parties have lately gone to work on old claims which have been idle for years.

ALASKA.

IREMS.—The Stewart mine at Sitka lately shipped \$1,600 in bullion, the product of a week's run of the five-stamp mill. Water-power is a failure from insufficiency. The Alaska G. & S. M. Co. have been advised by their superintendent to send up a 20-stamp mill immediately, with steam-power. The mountains are being prospected in every direction and new ledges discovered every day. Work on the Witch mine is progressing. Amaraas are being erected. Haley sold a third interest in the Haley & Hatch lode for \$7,500 to the Barcroft Island Mining Co. They will tunnel this winter, and commence a mill early in the spring. They also own the Witch and Cozian mines. A large quantity of ore is shipped to San Francisco from various lodes for a thorough test. Fresh arrivals of miners take place constantly, who all concur in the opinion of the good character of the quartz. Much fine gold is in some veins. The Barcroft Island Mining Co. are now erecting a storehouse and wharf, preparatory to extensive operations in the spring. Reports from Cassiar are discouraging. Nothing new has been found, and the old claims are worked out. The miners are leaving for the Sitka quartz mines.

COLORADO.

ALMA.—Denver Tribune, a correspondent says: Large bodies of low-grade carbonate ore have been discovered in a number of shallow openings in the timber just above town. The ore as exposed is from 2 ft to 6 ft in thickness, and assays from 12 to 60 ounces in silver, and 15% to 60% in lead. At least 10 to 12 openings in Buckskin spur of Mount Bross that extends to the town of Alma show the above amounts and character of ore. The output of the Fanny Barrett shaft for Saturday, the product of the labor of three men for driving a drift, was seven tons of good smelting ore. This was without stopping. A drift was shoved down in the sand carbonate for about 5 ft below the bottom of the shaft. Hundreds of tons of ore are now exposed in this new mine. A fine body of good-looking sand ore has just been struck in the Kansas Extension mine at the depth of 23 ft. The Avalanche mine, adjoining the Loveland mines, has just been sold under an old bond at \$5,000, while \$50,000 was offered for it if the bond could be broken. The Blackhawk mine, in Pennsylvania gulch, has from 3 ft to 5 ft of ore that mill-runs from 50 to 350 ounces of silver per ton.

LITTLE PITTSBURG.—Boulder News: The pay streak in this mine averages about a foot in width, and carries a grade of tellurium rich enough to ship without sorting.

PARK CO.—Fairplay Flume: New discoveries in Buckskin gulch yield large assays. On the Bross Mountain above the mine, the exterior is a goodly one, particularly on the Duke. For 70 ft in width at one point on the surface the rock may be broken anywhere and the fracture will disclose bright galena all through it. The ore lies in a well-defined vein for a width of 25 ft, the balance of the "blow out" being mineralized country rock. The vein material is alleged to average over 30 ounces in silver and 55% in lead.

IDAHO.

IREMS.—Oueda County Enterprise: Rich mines are said to have been discovered at Alturas Lake. The Montana yields a high standard of ore, in a 6-ft vein. The Badger mine shows a 9-ft vein of ore. Assays at from \$200 to \$600 per ton. In the Charles Dickens a new tunnel has been driven into the hill, at a point 100 ft below the old ore and road level. The placer miners on the upper Snake river are doing moderately well. The silver-plate process is the best adapted to saving the four gold.

IREMS.—Statesman: An old man prospecting on Dry creek has struck a lead about eight miles from town (Boise City), and went down in it 10 ft, finding a base metal lead 8 ft wide.

YANKEE FORK.—The ledge on the Custer lead is shown by a tunnel to be 600 ft in depth from the apex of the outcropping.

ALTURAS.—Rich and extensive discoveries are said to have been made on the headwaters of Wood river. Seventy-five men are operating in the mountains around the Salmon lake. Eighteen miles from Atlanta, on the Bonanza City trail, several rich mines have been opened, largely composed of ruby and native silver.

MONTANA.

IREMS.—Helena Independent: Several parties who have been prospecting for two years on the Bald butte, one-half mile south of the Penobscot mine, have at last struck a vein about 20 ft from the surface. It has a width from 6 to 14 ft. The ore is very rich. On Wisconsin creek, near Sheridan, McConnell & Co. are running an arrastra on \$20 ore from the Anna. Parties are running a hydraulic on a bar below the canyon, and doing well. The Company mine has a new shaft, and the placer miners on the Snake river tunnel of this mine taps the vein which is three ft wide, 150 ft from the surface. Ore from the Plymouth Rock averages \$20 per ton working with an arrastra. Numerous quartz and placer mines are being worked along this creek. The new diggings at Yago gulch, Meagher county, on which are located the Judith mines, are 65 miles from Judith City, 105 from Bozeman and 100 from Helena. The whole gulch is about all staked. Sluices are being put in.

NEW MEXICO.

IREMS.—Grant County Herald, Sept. 17: Some prospectors, who left Georgetown three weeks ago, have returned, bringing some very good-looking specimens of gold and silver quartz. Parties have been prospecting through the mountains to the north and east of the Mimbres report that they have discovered and located some mines which had fair to prove to be not only rich but abundant in quantity of ores. The formation being granite and the veins being large on the surface, every indication is that they will be paying mines. Bremen's mine is said to contain a body of ore reaching out of sight in all directions, and running from 80 to 85 per pound. The Mariano and Sandia mining district is yielding rich specimens of ore.

The rock assays from \$50 to \$200 per ton. At Corrallos the leads are improving. The latest assays of the Oread give 305 ounces to the ton. The Condor is 20 ft deep. The Carbonate, 140 ft, improving more. F. L. Alden, an old miner from Oregon, has a rich find of blue chlorides of silver; the first one of the kind in this camp. The Red Jacket lode belonging to the Essex Co-operative Mining Association, has a 2-ft crevice, with a 22-inch pay streak; it appears to carry a large quantity of native silver; this is the best mine in the northern part of this district.

OREGON.

VIRTUE MINE.—Bedrock Democrat, Sept. 17: The steam pump on the 400 level forces a continual stream of about 25 inches from the mine. The ledge has been stoped several hundred ft in length and over 300 ft in height. Sinking the main shaft is about being commenced.

C. F. M. Co.—Oregonian, Sept. 20: Specimens of gold and silver-bearing quartz were left at this office Wednesday, taken from the ledge of the Canal Fork mining company. This ledge has been worked a little for the past three years, but active operations were inaugurated only about three months ago. The ledge is located in the Cascade mountains, about 30 miles from Mahama and two miles from the White Bull. The ledge varies in width from 18 inches to 3 ft, and is well defined. Quartz taken from this ledge has been assayed in this city and yields from \$150 to \$250 per ton. Bernard and Vonach are the superintendents.

A Gold Gleaner.

We have been shown a model of a device for saving gold and other precious metals that will doubtless ultimately work its way into favorably use, and he worthy of the appellation of "Gold Gleaner," which has been given it. Since the inventor, Mr. Bryan Tyson, over five years ago, constructed the first device of this kind, important and valuable changes have been made. It is especially designed for saving fine gold and rusty gold, black sand, sulphurets, etc., from the tailings of either quartz or hydraulic mines. Much gold is, as Mr. Tyson believes, lost by attempting to save it in the midst of too much sand, or similar substances. His device, as now improved and remodeled, consists, in the first place, of a suitable arrangement for skimming, or rather cutting, out a thin stratum from the bottom of the flowing sands. To prove the efficiency of this plan, he cites his experiment at Bodie of August, 1878. In his first experiment he worked the whole amount of tailings as they flowed from the mill, and in two days took in amalgam and sulphide of silver to the amount of some \$13. He then changed his device so as to work only a thin stratum of tailings taken from near the bottom, and in other two days took over \$100, having increased his catch nearly eight-fold. It is a model of this device, since greatly improved and reduced to machinery, of which we now speak.

The next feature consists in a simple and effective device for keeping the sands between ordinary riffle bars loose, thus apparently presenting all necessary facilities for the precipitation and settling of the precious metals to a place of safety. This device, as Mr. T. tells us, has only been partially tested, and yet answered an excellent purpose in saving both gold and quicksilver. Recent improvements, as pointed out to us, will doubtless render it far more effective.

The next feature is a concentrating pan, worked as a jigger. The most important feature about this is its construction for stirring the sands near the surface, thus greatly facilitating the settling of the precious metals, or other heavy substances. It is especially designed for saving black sand, sulphurets, and such of the precious metals as may have escaped the devices above. It was Mr. Tyson's intention to attach a device of this kind to his works at Gold Run, but he was not able to complete it before the rainy season set in, and it has therefore not been tested. The fundamental principles thereof have, however, been so thoroughly tested in other experiments that he considers there can be little or no doubt as to the result.

He has also shown us a model of his device as now constructed at Gold Run. The principle involved is mainly the same as in the foregoing—keeping the sands between riffle bars loose by appropriate machinery—but as this method only procured concentrations, such as may be procured by his new method without machinery, it has been abandoned for the far more simple and cheaper as well as more effective method above described.

Some splendid results were, however, obtained from some of the early experiments with the device abandoned, but the construction was such as to render it tedious to clean up, and it was therefore impractical for general use. As now amended and improved it can be cleaned up as easily as an ordinary under-current.

Some of the most important features of the portion abandoned, that actual tests have shown to be of great value, in fact indispensable, will still be retained in the new device. Rigid tests will doubtless find the Gold Gleaner to be possessed of considerable merit, and important results may therefore be expected in the near future.

A MIRROR BAROMETER.—M. Leon Tesserenc de Bort has ingeniously modified the common aneroid barometer by substituting for the train of clock-work terminating in a pointer, a mirror mounted on a jeweled axis, which is rotated by the rise and fall of the exhausted receiver, and its indications read off by a small telescope by reflection from a graduated scale. The sensibility of the instrument is said to be much increased, and all errors due to a long train of wheel-work are eliminated.

Carribou Gold Mining District.

We learn from the Idaho Enterprise that this is a comparatively new mining district of Oneida county, Idaho. It takes its name from Carribou mountain, which rises abruptly some 10,000 feet, and is the highest of Snake River chain. The hills and gulches are full of prospect holes, and the ground is nearly all located for several miles around Iowa har. There is said to be plenty of pay dirt, but water is scarce. The best worked placer digging is that of Sweeney & Feeney, at Iowa bar. They have the best water privilege and plenty of it for working all the year round. Their ditch extends up the mountain side for over two miles, is fed by strong and never-failing springs, and when thrown through the three-inch nozzle pipe at a bank of dirt it crumbles away very rapidly. Even large boulders are carried away by the force of the current from the pipe for rods. They play this pipe on the bank until several tons of dirt are caved down, and then wash it all away, leaving the gold to settle to the bottom; it is then washed out into the sluice ways, and cleaned up every week or as often as desired. It is said that they net about \$50 per day.

The Robinson mine is located on the north slope of the mountain, bears southeast and northwest, and where a crosscut shows 18 feet of a ledge of degenerated sulphure ore. The predominating element of all quartz veins in this district is iron, both as a sulphide and sulphure, and in its contact with the organic elements of the earth has turned into a red dust. This being strongly charged with silver and gold, is amalgamated together in veins. These veins are in this district from 6 to 20 feet in thickness, and are all gold-bearing but not very rich, as but few if any of the veins sampled so far run over \$100 to the ton, but there being such immense bodies of ore, and wood and water being handy, they will pay richly to work. The Robinson mine must have about 1,000 tons on the dump and several thousand tons in sight, and is only waiting for a 40-stamp mill to be erected close by to insure the owners a fortune. It is owned by John Robinson, John Tierman and Joseph Farran, the latter two gentlemen residents of Salt Lake city. We understand they are looking to the erection of a mill during the early part of next season.

In other miness tunneling has disclosed either the same vein or ore of the same character as the Robinson mine. All of the ledges are of great thickness and an immense supply of ore. The placer mines of this district are rich and extensive, and its quartz veins are immense and easily and cheaply worked, and rich enough to pay large profits to the owners of the mines and mills. What it needs is mills to work up the ore, of which the whole mountain seems to be composed.

California Balloon Bush.

A matter of much interest to botanists and perhaps to growers of interesting ehubs is the rediscovery by Prof. J. G. Lemmon, of Sierra Valley, of the long lost "Balloon bush" of California (*Staphylea Bolanderi*, Gray.) This curious bush was first found by Prof. Bolander many years ago, but he found it only in bloom and the description in the first volume of the Botany of California is meager from this fact. There has been an eager demand for fruiting specimens of the shrub, and thorough search has been made, but it has eluded the pursuer until a few weeks ago Prof. Lemmon found it after a long day's search up and down the McCloud river near Mt. Shasta. It was in full fruit and Prof. Lemmon has arranged to have the seed collected. The announcement of the rediscovery has excited a storm of inquiries and expressions of gratification from Eastern botanists.

The balloon bush of California is of especial botanical interest because it belongs to a genus (*Staphylea*) which contains but four species beside it, and the geographical distribution of these four species is quite remarkable. One is indigenous to the Eastern States, another in Western Europe, another in Himalaya mountains of India, and the fourth in Japan. Prof. Lemmon gives us some points in description of the California species which indicate that it would be a most interesting shrub for ornamental grounds in this climate. The shrub or tree itself somewhat resembles the ash, having an orbicular leaf, but its leaves are grouped in threes unlike the ash. It grows from four to ten feet high and has a striking appearance. The young branches are of clean straight growth and suggest a fitness for walking canes. But the most interesting part of the shrub is the fruit which has been so long sought for. It is an inflated three-angled halloon from two to three inches long and pendent like a pear. These balloons hang in clusters of three or more. They are of light green color when growing and turn chestnut colored when mature. When mature they remain persistent on the limb through the winter. They contain from three to six large, hard, black seeds which become detached and rattle in their dry case when the wind stirs the branches. Thus the dry fruit may be likened to a rattle box. The flowers are of whitish color, half an inch in diameter and borne upon a pendent raceme.

Such in brief is a very interesting indigenous shrub which may ere long become an interesting object on our lawns through Prof. Lemmon's persistent research and fortunate discovery.

News in Brief.

SECRETARY SCHURZ is in the Indian Territory. THERE is a prospect of war between Egypt and Abyssinia.

A MINISTERIAL crisis has occurred in the Argentine Republic.

The Bank of Montreal is charging 20% discount on British silver.

The slaves of Cienfuegos, have risen in rebellion against the Spaniards.

ENGINEERS and machuists are leaving England for the United States.

THE reports regarding the famine in Cashmere are still very gloomy.

THE work of connecting the Black and Caspian seas has been commenced.

RICH lead discoveries are reported from Clark and Hot Springs counties, Arkansas.

LAST Saturday 50,000 bushels of grain was shipped from New York for Europe.

LORD LORTUS opened the Industrial exhibition at Sydney on the 22d inst.

It is estimated that 1,500,000 gallons of wine will be made in Napa valley this season.

THE strike of the colliers in Staffordshire has been ended by the masters yielding.

J. WARREN WOODWARD, Justice of the Supreme Court of Pennsylvania, is dead.

EXTENSIVE deposits of almost pure gypsum have been discovered near Seattle, W. T.

THE negroes continue to migrate to Kansas. Cheap rates are offered them on railroads.

SILVER in London, 51½d; consols, 97 11-16; 5% U. S. bonds, 105½; 4s, 104½; 4½, 103½.

SINCE January 1st the arrival of gold at New York, from Europe, amounted to \$27,000,000.

AT LIVERPOOL, wheat is quoted at 9s@9s 9d for average California white, and 9s 9d@10s 3d for club.

THE colored people celebrated the issuance of the Emancipation Proclamation at Chicago on the 22d.

FORTESQUE, an American, has been sentenced at London to ten years' penal servitude for forgery.

THREE men at Louisville ate toadstools for mushrooms. One died, the others are in a critical condition.

THE clipper ship *James Nesmith* is nearly loaded and will leave New York for San Francisco Saturday.

H. DEL BONDIO & Co., heavy exporters of grain at New York, have failed. Western firms lose heavily.

EMPEROR WILLIAM received a cool reception from the French-speaking portion of the population at Strashourg.

A CONGRESS in the interest of America is in session at Brussels. The King of Belgium and President Blanco of Venezuela were present.

"LORD MURPHY," the three-year-old colt that captured the Derby and St. Leger victories, has been purchased by James Keene for \$10,000.

IN SAN FRANCISCO, half dollars are quoted at 99½ buying, 99½ selling; trade dollars, 97 buying, 98 selling; Mexican dollars, 90 buying, 91 selling.

THE French Scientific Association speaks encouragingly of the future of American wines, and says the two great defects are virgin soil and inequality.

THE news of the outbreak at Herat, Afghanistan, is confirmed. The Governor's house was plundered and burned, and the commanding General murdered.

REV. THOMAS GUARD, of San Francisco, has been called to his old post as pastor of the Mount Vernon M. E. church, of Baltimore, and has signified his acceptance.

IN NEW YORK, Government bonds are quoted at 102½ for 4s of 1907; 102½ for 5s of 1881; 105 for 4½s; sterling, \$4.82@4.84; silver bars, 112; silver coin, ½@1 discount.

THE Rancho El Sobrante case is now awaiting the final decision of the Department at Washington. Should the Surveyor-General's opinion be adopted it will give all bona fide claimants the land occupied by them.

THE grain house of Smith, Howell & Co., Philadelphia, failed on the 22d, with liabilities at \$200,000. The failure is owing to the increase in the price of grain the past few days.

I. Jenks Smith, head of the firm, is President of the Commercial Exchange.

FIRELESS LOCOMOTIVES.—At the recent meeting of the British Association for the Advancement of Science, M. Bergeron read a paper on Leon Franco's fireless locomotive. The idea of such a locomotive was originated at the time of the horse plague in New Orleans, in 1872. After the Franco-German war, M. Franco, who was connected with the Paris tramways, gave his attention to discovering a motive power for his tramcars. The object he had in view was the obtaining such heat from water as would supply the motive power he needed. The engine in question was the result of his investigations. It had a large cylindrical reservoir, surmounted by a steel dome, two cylinders acting with piston rods, and a crank carrying two driving wheels, which were connected with other two wheels. The reservoir holds more than 700 gallons of water, heated to such an extent as to produce a pressure of 224 pounds to the square inch. It was claimed for the new engines that they were very economical in every respect. It was pointed out that the engine would be especially useful on the metropolitan lines, as it neither gave off smoke nor deleterious gases. In a few weeks an engine of this character would be used on the tramway at Leeds, and another at Liverpool docks. These engines are largely used on the French plantations in the West Indies.

Birth of a Storm.

In a lecture delivered by Robert H. Scott, M. A., F. R. S., etc., at the London Institution, he declares that storms are almost without exception foreshadowed. It has been claimed by Dove that storms are due to the interference of the Polar current, or the east wind, with the equatorial current, or west wind. The east wind being air flowing from the north or south pole toward the equator, and the west wind, the air endeavoring to make its way back to the pole from the equator, both being modified in the direction of their motion by the change of latitude.

This view has been superseded of late years by the modern view of the relation between the wind and the distribution of barometrical pressure. We are still, however, in comparative ignorance of the ultimate causes to which this distribution of pressure, or the rise and fall of the barometer, are due.

Various theories have been propounded to account for storms which are generally more or less cyclonic in their character. Ley, and others, attribute the formation and progress of a storm to the condensation of moisture, ignoring the fact that many of our heaviest rains do not give rise to cyclonic disturbances of serious character, and frequently come in times of nearly absolute calm.

Mr. Meldrum, of the Mauritius, through investigations into the weather over the Indian ocean, is led to the belief that every cyclone is generated in the intervening space between two oppositely flowing currents of air, of which the easterly moving stream, speaking in general terms, lies on the polar side of the westerly wind. This view, however, was called seriously in question by Messrs. Blanford & Eliot, in their discussion of recent cyclones in the Bay of Bengal, which they have been able to study from very early stages, and in which they fail to see evidence of the pre-existence of two, and only two, determinate currents.

M. Faye, of Paris, in a third theory of the origin of these storms, argues strongly that, as interfering currents in rivers give rise to vortices which extend from the surface downward into the water, so all our water spouts, *trombes*, and even the largest tropical hurricanes, must be all formed in the upper regions of the atmosphere, and extend downward to the earth; the force which gives them their onward motion being supplied by the upper currents.

This theory is not accepted because recent investigation into the motion of cirrus clouds, shows beyond a doubt that the motion of the upper currents of air over a cyclone is outward and not inward. Moreover, very lately there was observed, on the Lake of Geneva, a veritable small waterspout, 40 feet high, and 30 feet in circumference, formed by the meeting of two winds, known locally as the *Foehn* and the *Bise*, on the surface of the lake.

The last theory is that of the late Thomas Belt, who assumed as the first cause the heat of the sun. The heat rays pass through the atmosphere without warming the upper strata, and so Mr. Belt supposed that over a sandy soil a mass of air close to the ground might rise in temperature much higher than the superincumbent layers of the atmosphere, sooner or later the heated lower air would burst up, and the ascending column thus produced would be the nucleus of the nascent cyclone. Accredited instances of whirlwinds over volcanoes like San-torin, and over extensive fires like those of Carolina can be traced to be facts in favor of this theory. From other prominent facts attending the production of a cyclonic disturbance, the origin thereof may be attributable to more than one agency, as all the theories have some facts in their favor. Prof. Scott declares that it is a mistake to assert that all storms are connected with cyclonic disturbances. The force of the wind depends on differences of atmospheric pressure over a given area, and the only reason why storms are generally associated with cyclones is that these systems afford the most serious instances of disturbances of atmospheric equilibrium, and consequently of differences of pressure, which are met with on the globe. At any place where an area of relatively high pressure comes into close proximity to an area of relatively low pressure, a gale will result, and so a storm may be due just as much to the rise of the barometer in one region as to its fall in an adjacent one. Wherever there is a rapid decrease there is a steep gradient, and consequently a strong wind.

Every cyclone is not accompanied by a storm. The cyclone, in its general terms, simply indicates a region of diminished pressure, round and in upon which the air moves in paths. The direction and force of the wind are regulated by the difference of barometrical pressure over a given distance, and not by the actual height of the barometer at the station at which the storm is felt, or by the distance of that station from the point where the barometrical reading for the time being is the lowest.

The principles of wind motion have a most important bearing on the theory of the motion of the air in hurricanes and typhoons. The old popular idea was that the air blew round and round the central calm in circles, so that any sailor caught in one of these storms, if he was scudding before the wind, the center would lie exactly on the starboard beam in the northern, and on the port beam in the southern, hemisphere. Modern meteorologists, however, declare for a spirally inward movement as the most

probable behavior of the wind; and this suggestion of spiral motion must, of course, modify the simple rule for a ship when scudding, of looking in the wind's eye, and taking eight points on the starboard or port side for the storm center, and indicates the probability that the true position of that spot will be at least two or three points ahead of the bearing given by that rule, so that the ship, if scudding, may be gradually approaching the most dangerous part of the storm.

As yet meteorologists have been unable to produce evidence of the birth of a storm, neither has anyone been fortunate enough to be in at the death of one. Some claim that storms can travel all around the world, until at last they travel off.

They have been traced from the Pacific coast across the Atlantic, but very rarely. This fact, however, favors the condensation theory of storm generation, since it is held that, as the moisture in the air is the food of the storm, so, when that moisture is deficient, the storm dies of starvation. We may, however, point out the dust-whirls at street-corners, which waste and wane without any assistance from vapor condensation. We do not yet know why one depression in the atmosphere fills up, while another becomes deeper. What causes the barometer to rise or fall, is still an unsolved problem.

Every new subscriber who does not receive the paper, and every old subscriber not credited on the label, within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect ourselves and subscribers against the acts and mistakes of others.

Back Numbers Wanted.

The following volumes and single copies of the MINING AND SCIENTIFIC PRESS are wanted at this office, for which a reasonable price is offered:

Year.	Volume.	
1870	20	2 Complete volumes, 1st half of year.
1870	20	2 Copies of No. 2, Jan. 1st.
1870	20	1 Copy each of No. 1, Jan. 1st, 3 of Jan. 14th, 7 Feb. 11th, 6 Feb. 4th.
1870	21	1 Copy of No. 7, August 18th.
1871	22	5 Copies of No. 1, Jan. 7th.
1871	22	3 Copies of No. 5, Feb. 4th.
1871	22	1 Copy of No. 3, Jan. 21st, 6 of Feb. 2d, and 1 of May 1st.
1871	23	1 Copy of No. 2, July 15th, and 9 Sept. 2d.
1872	24	2 Copies of No. 4, Jan. 27th.
1872	24	3 Copies of No. 7, Feb. 17th.
1872	24	2 Copies of No. 17, April 27th.
1872	25	1 Copy of No. 1, Jan. 1st.
1872	25	1 Complete volume, last half of year.
1873	26	3 Copies of No. 8, Feb. 22d.
1873	26	3 Copies of No. 9, March 1st.
1873	26	2 Copies of No. 10, March 8th.
1873	26	1 Copy of No. 7, Feb. 15th.
1873	27	3 Copies of No. 20, Nov. 15th.
1873	27	4 Copies of No. 21, Nov. 22d.
1873	27	3 Copies of No. 24, Dec. 13th.
1875	30	1 Copy of No. 4, Jan. 23rd.
1875	30	1 Copy of No. 5, Jan. 30th.
1875	30	1 Copy of No. 8, Feb. 20th.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send one but worthy men.

J. L. THARP—San Francisco.
B. W. CROWLEY—California.
A. C. KNOX—Pacific Coast.
S. V. BLAZER—State of Nevada.
G. W. McGREW—Santa Clara county.
MILTON KENNEDY—Kern and Inyo counties.
J. B. BACHMANN—Shasta County, Cal.
H. H. MESSINGER—Arizona.

Quicksilver Mining Publication.

Memor on the Mines and Works of Almaden, by M. H. Kuss, M. E. Translated from the "Annales des Mines" for the MINING AND SCIENTIFIC PRESS, by S. B. CHRISTY.
CONTENTS.—PART I.—Geological Description of the Deposits at Almaden: 1. Introduction; 2. Geological Situation and Constitution; Silurian system; Devonian system; Eruptive Rocks; 3. Deposits of Mercury. Description of the Mine; Mineralogical Constitution of the Vein Matter; Age of the Veins; Abandoned Mines. PART II.—Exploitation of the Mines of Almaden: 1. Method of Exploitation; 2. Organization of Labor; 3. Mechanical Preparation. PART III.—Metallurgy of Mercury at Almaden: 1. Description of the Works; 2. Treatment of the Ore; 3. Losses of Treatment. PART IV.—Administration and History: 2. History; 48 large pamphlet pages, post-paid, 50 cents. DEWEY & CO., Publishers, S. F., 1879.

FRESH attractions are constantly added to Woodward's Garden, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

How to STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

REDDING, July 12th, 1879.
MESSRS. DEWEY & Co.—Gentlemen:—Have received my letters patent for the bar roller to-day. I am very much obliged to you for your prompt service, and will recommend you to all who may want your assistance.
I remain yours, etc.,
GEO. MEDINO.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

CHAS. E. LOCKE.....Lasses and Manager

PYRAMUS AND THISBE.

Open every evening and Saturday Matinee.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

The Pacific Land and Trust Company.

Location of principal place of business and works, San Francisco and State of California.

Notice is hereby given that at a meeting of the Board of Directors held on the eighteenth day of September, 1879, an assessment (No. 1) of One Dollar and Twenty-five cents per share was levied upon the capital stock of said corporation, payable immediately to the Secretary at the office of the company, 513 California street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on Saturday, October twenty-fourth (24th), 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before will be sold on Saturday, November eighteenth (18th), 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. W. M. ANDREWS, Jr., Secretary. Office, 513 California street, San Francisco, Cal.

Butte Hydraulic Mining Company.—Prin-

cial place of business, San Francisco, California. Location of works, Butte county, California.

Notice is hereby given, that at a meeting of the Board of Directors held on the 25th day of August, 1879, an assessment of Ten Dollars per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary, at the office of the company, Room 20, No. 328 Montgomery street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the 25th day of September, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before will be sold on Tuesday, the 25th day of October, 1879, to pay the delinquent assessment, together with the cost of advertising and expenses of sale.

L. L. DENNERY, Secretary.

Office, Room 20, No. 328 Montgomery st., S. F. Cal.

Gover Mining and Milling Company.—

Location of principal place of business, San Francisco, California. Location of works, near Drytown, Amador County, California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 30) levied on the sixth (6th) day of August, 1879, the several amounts set opposite the names of the respective shareholders as follows:

Names.	No. Certificate.	No. Shares.	Am't.
Ashby, Mark F. Trustee.....	907	1341	\$670 50
Ashby, Mark F. Trustee.....	908	890	400 00
Brayton, M. L.....	847	4 00	200 00
Brayton, M. L.....	901	115	57 50
Gorrie, Thomas.....	682	10	5 00
Pratt, Freeman.....	406	10	5 00
Prishie, Edward E.....	480	45	22 50

Skinner, E. C.....	441	100	50 00
Skinner, E. C.....	419	100	50 00
Skinner, E. C.....	620	50	25 00

And in accordance with law and an order of the Board of Directors, made on the sixth (6th) day of August, 1879, so many shares of each parcel of such stock as may be necessary will be sold at public auction at the office of the company, room 8, No. 402 Front street, San Francisco, California, on Monday, the sixth (6th) day of October, 1879, at the hour of one (1) o'clock P. M. of such day, to pay delinquent assessments thereon, together with costs of advertising and expense of the sale.

W. O. WILSON, Secretary.

Office, Room 8, No. 402 Front street, San Francisco, Cal.

Annual Meeting.—Syndicate Mining Co.,

of Bodie, Mono County, California.

The annual meeting of the above named Company will be held at the office, Room 36, Hayward Building, 419 California street, San Francisco, Cal., on Thursday, October 16th, 1879, at 1 o'clock P. M., for the purpose of electing a Board of Directors to serve for the ensuing year, and for the transaction of such other business as may properly come before the meeting. Also in accordance with a resolution adopted at a meeting of the Board of Directors, held September 15th, 1879, to take into consideration and decide upon the proposition to increase the capital stock of said Company, from Five Million Dollars divided into fifty thousand shares at the par value of one hundred dollars per share, the present capital of the Company, to Ten Million Dollars, to be divided into one hundred thousand shares of the par value of one hundred dollars each.

THOS. G. TAYLOR,
ROBT. N. GRAVES,
GEO. W. HOPKINS,
CHAS. H. FISH,

The transfer books will be closed October 6th, 1879, at 3 P. M.

JACOB STADTFELD, Jr., Secretary.

Canadian Patents for U. S. In-

ventors and Patentees.

One Patent now Embraces all the English

Iron and Machine Works.

THOS. PENDERGAST.

HENRY S. SMITH.

ÆTNA IRON WORKS,

MANUFACTURERS OF

IRON CASTINGS

and MACHINERY

OF ALL KINDS.

Fremont Street, bet. Howard and Folsom,

SAN FRANCISCO.

SACRAMENTO BOILER WORKS,

214 & 216 BEALE St., (rear of Ætna Foundry)

J. V. HALL,

PRACTICAL BOILER MAKER,

Marine, Stationary and Portable Boilers, Smoke Stacks, Hydraulic Pipe, Oil or Water Tanks, Ore and Water Buckets, Gasometers, Girders, Bridges and Iron Ship Building.

ALL KINDS OF SHEET IRON WORK.

Repairing promptly attended to at the lowest possible terms.

UNION IRON WORKS,

SACRAMENTO, CAL.

ROOT, NEILSON & CO.,

MANUFACTURERS OF

STEAM ENGINES, BOILERS AND ALL

Kinds of Machinery for Mining Purposes.

Flouring Mills, Saw Mills and Quartz Mills Machinery constructed, fitted up and repaired.

Front Street, Between N and O Streets, SACRAMENTO, CAL.

PHELPS

MANUFACTURING COMPANY,

Manufacturers of all kinds of

Wharf and Bridge Bolts, Railroad Trestle Work, Car Frames and Bolts, Machine Bolts, Set Screws and Tap Bolts, Lag or Coach Screws.

ALL STYLES OF FANCY HEAD BOLTS.

HOT AND COLD PRESSED HEXAGONAL AND SQUARE NUTS, WASHERS, BOLT ENDS, TURNBUCKLES, ETC., ETC.

13, 15 and 17 Drumm St., near California,

SAN FRANCISCO, CAL.

Golden State & Miners Iron Works,

Manufacture Iron Castings and Machinery of all Kinds at Greatly Reduced Rates.

STEVENSON'S PATENT

Mold-Board AMALGAMATORS,

Golden State Pressure Blowers.

First St., between Howard & Folsom, S. F.

California Brass Foundry,

No. 125 First Street, Opposite Minna.

SAN FRANCISCO, CAL.

All kinds of Brass, Composition, Zinc, and Babbitt Metal Castings, Brass Ship Work of all kinds, Spikes, sheathing Nails, Rudder Braces, Hinges, Ship and Steamboat Bells and Gongs of superior tone. All kinds of Cocks and Valves, Hydraulic Pipes and Nozzles, and Hose Couplings and Connections of all sizes and patterns, furnished with dispatch. PRICES MODERATE. J. H. WEED. V. KINGWELL.

WM. H. BIRCH.

JOHN ARGALL.

California Machine Works,

BIRCH, ARGALL & CO.,

119 Beale Street, San Francisco.

General Mechanical Engineers and Machinists. Steam Engines, Flour, Quartz and Mining Machinery. Sole manufacturers of Brodie's Patent Rock Crushers and Steel-Faced Tappits. Agents and Manufacturers of F. A. Youss's Patent Steam Packing Rings for Steam Pistons. The best ever invented; can be applied to any Piston Engines in true satisfaction by those using. Steam, Hydraulic and Sidewalk Elevators. Repairing promptly attended to.

STEAM ENGINES AND BOILERS

Of all sizes—from 2 to 60-Horse power. Also, Quartz Mills, Mining Pumps, Hoisting Machinery, Shafting, Iron Tanks, etc. For sale at the lowest prices by

J. HENDY, 49 and 51 Fremont Street, S. F.

THOMAS THOMPSON.

THORNTON THOMPSON.

THOMPSON BROTHERS,

EUREKA FOUNDRY,

129 and 131 Beale St., between Mission and Howard, S. F.

MANUFACTURERS OF CASTINGS OF EVERY DESCRIPTION.

WIND MILL. One of the best made in this State for sale cheap on easy terms. Address, W. T. care of Dewey & Co., S. F.

William Hawkins,

(SUCCESSOR TO HAWKINS & CANTRELL).

MACHINE WORKS,

210 and 212 Beale Street, bet. Howard and Folsom Sts., - - San Francisco.

Manufacturer of

IMPROVED PORTABLE HOISTING ENGINES,

FOR MINING AND OTHER PURPOSES.

Also of the HAWKINS' PATENT ELEVATOR HOIST, for Hotels, Warehouses and Public Buildings.

Steam Engines and all Kinds of Mill and Mining Machinery.

Fulton Iron Works.

Hinckley, Spiers & Hayes.

(ESTABLISHED IN 1855.)

Works, Fremont and Howard Sts. | San Francisco, Cal. | Office, No. 213 Fremont St.

MANUFACTURERS OF

Marine Engines and Boilers,

Propeller Engines either High Pressure or Compound Stern or Side Wheel Engines.

Mining Machinery.

Hoisting Engines and Works, Cages, Ore Buckets, Ore Cars, Pumping Engines and Pumps, Water Buckets, Pump Columns, Air Compressors, Air Receivers, Air Pipes.

Mill Machinery.

Batteries for Dry or Wet Crushing, Amalgamating

Engines and Boilers

of all kinds, either for use on Steamboats and made in accordance with the Act of Congress regulating the same, or for use on land. Water Pipe, Pump or Air Column, Fish Tanks for Salmon Canneries of every description. Boiler repairs promptly attended to and at very moderate rates.

Pans, Settlers, Furnaces, Retorts, Concentrators, Ore Feeders, Rock Breakers, Furnaces for Reducing Ores Water Jackets, Etc.

Sugar Machinery.

Crushing Rolls, Clarifiers, Vacuum Pans, Air Pumps, Concentrators, Bag Filters, Charcoal Filters, Blow-up Tanks, Coolers and Receiving Tanks.

Miscellaneous Machinery.

Flour Mill Machinery, Saw Mill Engines and Boilers, Dredging Machinery, Oil Well Retorts, Powder Mill Machinery, Water Wheels.

Pacific Rolling Mill Co.,

SAN FRANCISCO, CAL.

MANUFACTURERS OF

RAILROAD AND MERCHANT IRON,

ROLLED BEAMS, ANGLE, CHANNEL AND T IRON, BRIDOE AND MACHINE BOLTS, LAG SCREWS, NUTS WASHERS, ETC., STEAMBOAT SHAFTS, CRANKS, PISTONS, CONNECTING RODS, ETC., ETC.

Car and Locomotive Axles and Frames, and Hammered Iron of Every Description.

HIGHEST PRICE PAID FOR SCRAP IRON.

Orders Solicited and Promptly Executed.

Office, No. 16 FIRST STREET.

PACIFIC IRON WORKS,

First and Fremont Streets, between Mission and Howard, San Francisco, Cal.,

RANKIN, BRAYTON & CO.,

Manufacturers of

ENGINES, BOILERS, MARINE AND STATIONARY. PUMPING, HOISTING, AND MINING MACHINERY INCLUDING BATTERIES, AMALGAMATING PANS AND SETTLERS, CONCENTRATORS, ORE FEEDERS, CRUSHING ROLLS AND ROCK BREAKERS. ALSO, WATER JACKET SMELTING FURNACES, FOR REDUCING LEAD, SILVER AND COPPER ORES, QUICKSILVER FURNACES, RETORTS AND CONDENSERS, ROASTING AND CHLORIDIZING FURNACES, SUGAR MILL MACHINERY, WATER WHEELS, Etc., ALL OF THE LATEST AND MOST IMPROVED CONSTRUCTION.

Agents for the Allen Engine Governor, Bailey Air Compressor, Howell's Improved White Furnaces, Walker's Compound Steam Pumps, Etc.

Union Brass Foundry, And Mechanical Workshop.

Manufactures all kinds of Brass Goods, Plumbing, Brewery and Distillery Work, Gas and Soda Apparatus, Mining Goods, Ship Work, Steam Fittings, Water Gates and Valve Meters, Gauges, Counters, Indicators, etc.

MACHINE PATTERN and MODEL MAKING a Specialty. Bell and Brass Castings to order at shortest notice. Clock Work Ours cut to order. Highest Market Price paid for Old Metal. For particulars and price lists address

GIOVANNINI & CO.,

Nos. 417 and 419 Mission Street, - - San Francisco, Cal.

Corner Beale and Howard Sts.,

SAN FRANCISCO, CAL.

JOSEPH MOORE, Supt.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Captains, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER,

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

Main Street Iron Works,

WM. DEACON, PROPRIETOR.

Noe. 131, 133 & 135 Main St., San Francisco.

Stationary and Marine Engines,

Shafting, Pulleys, and General Machine Work. Jobbing and repairing done Promptly and at Lowest Rates. Screw Propellers, Propeller and Steamboat Engines.

SAW MILLS and SAW MILL MACHINERY.

A CARD.

To Parties Interested in Mining and Milling.

Call at J. HENDY'S, N. E. corner of Mission and Fremont Streets, San Francisco, and examine COLEMAN'S PATENT SLUICE. It will save both float and flour Gold. The best system yet devised. No power required to work it. Examine it and judge for yourselves before purchasing elsewhere.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

GOLD MINE WANTED.

One now paying more than expenses. Address

W. S. KEYES, M. E.,

No. 310 Pine St., Room 42, San Francisco

LAND Good land that will raise a crop every year. Over 14,000 acres for sale in lots to suit. Climate healthy. No drouths, bad floods, nor malaria. Wood and water convenient. U. S. Title perfect. Send stamp for illustrated circular, to EDWARD FRISBIE, Proprietor of Reading Ranch, Anderson, Sbaata County, Cal.

FRASER & CHALMERS
 STEAM ENGINES, BOILERS, STAMP MILLS, FRUE VANNERS
 (and Machinery) for Systematic Mining, Milling, Smelting and Concentration of Ores.
 No. 145 Fulton St., CHICAGO, ILL.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion, he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.
 No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street, - - San Francisco, Cal.

Patented June 25th, 1878.

SAVE YOUR GOLD And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

FRANCIS SMITH & CO.,

Manufacturers of

THE PATENT CHANNEL IRON WHEELBARROWS.

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

SHEET IRON PIPE.

Howe's U. S. Standard Scales.

SCALES REPAIRED

In City or Country by a Practical Scale Maker with United States Standard Weight.

DAVID N. HAWLEY, Agt., 201 and 203 Market Street, (Cor. Main) SAN FRANCISCO.

Trall Hygienic, Medical and Surgical Sanitarium.

No. 8 Ellis Street, San Francisco, Cal.

Treatment by a Purely Scientific and Rational Method Without Drugs of any Kind.

THE TREATMENT DEPARTMENT EMBRACES ALL APPROVED REMEDIAL AGENTS, AS OXYGEN INHALATIONS, VACUUM TREATMENT, THERMO-ELECTRIC, TURCO-AMERICAN, ELECTRO-MAGNETIC, GALVANO-CHEMICAL, STEAM VAPOR, WARM AIR, AND ALL FORMS OF WATER BATHS;

Swedish Movements, The Health Lift, Sphygmeter or Lung Strengtheners, Steam Atomizers, all Electric, Galvanic and Surgical Appliances, Sun Baths, and Solar Ray Surgery, new and perfect Truss for the Radical Cure of Hernia, lately discovered Chemical Compound for the speedy, safe, painless and permanent removal of Cancers, Scientific and successful method for the Cure of Piles, etc., etc.

It Aims to keep Abreast with, if not in Advance of the Progressive Age.

It has been the mission of this System to mold public sentiment and this Institution will hope to be no disgrace to the immortal name it has assumed. The time has come when Physicians of this School can afford financially to keep a conscience; in fact it is disastrous financially as well as morally to compromise the truth; one lot; hence patients can rest assured that they will be treated by the Physicians after the most approved and scientific methods, out of pure and enlightened selfishness, recognizing the truth and beauty of this great principle:

"The Universe is so ordered and arranged that the real and permanent good of every creature is best subserved in promoting the real and permanent good of every other being."

THE BOARDING DEPARTMENT.

The table will be supplied with the best the excelsior market of the world affords, embracing fruits, grains, vegetables, meats, fish, fowl, eggs, cream, etc. Regular and transient boarders will be accommodated as well as patients. Business and professional men and women who are tired of restaurant fare, may appreciate eating to live a more healthful and enjoyable life. Pure food means pure blood. Pure blood means good health.

"The vegetarian school has demonstrated beyond the possibility of a doubt that farinaceous dishes, sweet milk and fruit, are sufficient to maintain a hard working man in perfect health. Such a diet might, certainly, be substituted by sedentary people for their present diet."

The Rooms are pleasant, warm, well ventilated and sunny; convenient to treatment rooms, so as to afford the best advantage of nursing and professional attendance.

GENERAL PRACTICE.

Fevers, and in fact all cases may be treated at home successfully. Parturition, confinement cases are taken in the Institution or attended at home in any part of the city or country. Preparatory treatment in these cases is most important.

Testimonials of extraordinary cases and cures can be seen on application. The most desperate cases, and especially those that have been given up as incurable by the old methods, are invited. Febrile and typhoid fever and diphtheria cases, after all other methods have failed, may be said to be a specialty. Send for the TRALL HEALTH JOURNAL.

DRS. D. C. & MRS. E. D. MOORE,

Trall Hygienic Sanitarium, 8 Ellis St. S. F.

MINERAL LUBRICATING OILS.

Both Dark and Light in Color, and Gravities to Suit all Classes of Machinery.

For use in all Saw Mills, Flouring Mills, Quartz Mills, Foundries and Machine Shops, and Railroads.

Natural Dark West Virginia Lubricating Oils,

FROM 19 DEG. TO 23 DEG. GRAVITY.

LIGHT PARAFFINE LUBRICATING OILS FROM 24 DEG. TO 33 DEG. GRAVITY.

CYLINDER OILS for use in all Cylinders.

A Full Stock of LARD OIL, SPERM OIL and other Lubricating Oils constantly on hand. Also

High Fire Test Water White Illuminating Oils,

FOR USE WHERE ABSOLUTE SAFETY IS REQUIRED.

Oil House of F. B. Taylor & Co.,

From 1-4 to 10,000 lbs. Weight.

STEEL CASTINGS.

True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc. 12,000 Crank Shafts of this Steel now running proved superior to wrought iron. CRANK SHAFTS, CROSSHEADS and GEARING, specialties. Circulars and Price Lists free. Address

Chester Steel Castings Co.

Works, Chester, Pennsylvania. 407 Library St., Philadelphia

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot, PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

The Mi-wok Indians.

The Mi-wok is the largest Indian nation in California, both in population and extent of territory. Their ancient dominion extended from the snow-line of the Sierra Nevada to the San Joaquin river, and from the Cosumnes to the Fresno. The mountain valleys were thickly peopled as far east as Yosemite; the great and fertile San Joaquin plains, and the banks of the long fish-full streams of the Mokelumne, the Stanislaus, the Tuolumne, the Merced, the Chowchilla and the San Joaquin were anciently crowded with multitudes of these Indians. Even the islands of the San Joaquin were made to sustain their quota, for on Foatber Island there are said to be the remains of a populous village. The rich alluvial lands along the lower Stanislaus, Tuolumne and Merced contained the heart of the nation, and were probably the seat of the densest population of ancient California.

The language of the nation was more homogeneous than many others, not half so widely ramified. From the upper end of the Yosemite, traveling 150 miles with the sun, and from the Cosumnes southward to Fresno, there was scarcely a change of a syllable. There are, as always, many abrupt dialectic departures, but the root remains and is quickly caught by the Indian of a different dialect. They were nothing more than the different local pronunciations, such as are apparent in the English language, seemingly entirely different to a foreigner, but only an unimportant, well understood variation to a native.

North of the Stanislaus these people called themselves *mi-wok* ("man"); south to the Merced, *mi-wa*; on the Fresno, *mi-wi*. On the upper Merced the word "river" is *wa-kal-la*; on the upper Tuolumne, *wa-kal-u-mi*; on the Stanislaus and Mokelumne, *wa-kal-um-luh*. This is undoubtedly the origin of the word "Mokelumnes," which is locally pronounced "mo-kal-u-my" (accent on second syllable).

So also *kos-sum*, *kos-sum-mi* (salmon) is probably the origin of the word "Cosumnes," which is pronounced *koz u-my* (accent on first syllable). Although the largest, this is probably the lowest nation in California, presenting one of the most hopeless and saddening spectacles of heathen races.

They eat all creatures that swim in the waters, all that fly through the air, and all that creep, crawl, or walk upon the earth, with a dozen or so exceptions. They have the most degraded and superstitious beliefs in wood-spirits, who produce those disastrous conflagrations to which California is subject; in water-spirits, who inhabit the rivers, consume the fish, and in fetichistic spirits, who assume the forms of owls and other birds, to render their lives a terror by night and by day.

In occasional specimens of noble physical stature they were not lacking, especially in Yosemite and other mountain valleys; but the utter weakness, puerility, and imbecility of their conceptions, and the unspeakable obscenity of some of their legends, almost surpass belief.

A majority of all who have any well defined ideas whatever on the subject, believe in the annihilation of the soul after death. He was referred to as *itah*, representing the memory of a being that once was. While other tribes mitigated the final terror by an assured belief in a Happy Western Land, the Mi-wok go

down with a grim and stolid sullenness to the death of a dog that will live no more.

For houses the Mi-wok construct very rude affairs of poles and brushwood, which they cover with earth in the winter; in summer they move into mere brushwood shelters. Higher up in the mountains they make a summer lodge of puncheons in the shape of a sharp cone, with one side open, and a bivouac-fire in front of it.

The only special points to be noted in their physiognomy are the smallness of their heads, and the flatness of the sinciput, caused by their lying on the hard baby-basket when infants.

Major Stephen Powers, in Powell's Contributions to North American Ethnology, from which this sketch is taken, says: "I felt the heads of a rancheria near Chinese Camp, and was surprised at the diminutive balls which lurked within the masses of hair. The Chief, Captain John, was at least 70 years old, yet his head was still perceptibly flattened on the back, and I could almost encircle it with my hands."

For food they depend principally on acorns.

They had, in common with many tribes both in the Sierra and in the Coast range, a kind of

rows were bought of the upper mountaineers. White shell buttons, pierced in the center and strung together were used as money, rated at \$5 a yard; periwinkles at \$1 a yard.

Their chieftainship, such as it is, is hereditary when there is a son or brother of commanding influence, which is seldom; otherwise, he is thrust aside for another. The Chief is simply a master of ceremonies. When he decides to hold a dance in his village, he dispatches messengers to the neighboring rancherias, each bearing a string whereon is tied a number of knots. Every morning thereafter the invited Chief unties one of the knots, and when the last one is reached, men, women and children joyfully set forth for the dance.

Scarification and prolonged suction with the mouth are the staple methods of cure among their shamans or physicians, some of whom are women. In case of colds and rheumatism they apply California Balm of Gilead (*Picea grandis*) externally and internally. Stomachic affections are treated with a plaster of hot ashes and moist earth. The shaman's prerogative is that he must be paid in advance, usually fresh

An Unfortunate Affair.

At a time when there exists so much friendly rivalry among the various mining districts of the Rocky Mountain region, to build up a substantial and enduring business founded upon mining operations, and when the recent glittering developments of yellow metal which have occurred in every quarter have caused capital to seek the most favorable localities for investment, a conflict has arisen in a peculiarly desirable region, the merits of which we are not called upon to investigate. We refer to the difficulty existing between the Miners' Union and the Jupiter-Owyhee party. Whatever may be the causes which brought about the antagonism, however meritorious the principles involved, the idea has gone forth that Bodie has become a lawless community, and the individuals who have brought about such a condition of things will not alone be the sufferers. The entire district will feel it more or less, and feel it for a long time.

Men of means seeking investment are not going to walk up to the cannon's mouth to disburse their money, and there are too many good investments in which the individual will possess a feeling of personal safety of more value to him than the security of his money. The time for a reign of terror in any locality has passed, and even the least thoughtful can understand us when we say that deeds of violence, nay, an intimation, a probability of violence, will drive away that wealth which is so necessary to the development of any business relations. We do not believe that there is any cause to fear for the personal security of any well-behaved individual in any of our mining localities. In the early days when the rich deposits were more concentrated in territory, personal conflicts arose which were unavoidable by reason of the close human contact. Nay, the bullet seemed almost a necessity to preserve order, we will not say law; but there is no such

excuse now. The scandal has been created and cannot be recalled. We talk of rights and remedies and agree upon a system to determine them. We spend immense sums in taxes to maintain an official system, and hold out inducements to others to come and dwell among us, and a few persons in an insane moment take the law into their own hands and all our previous labor in building an orderly structure is lost. There is nothing in such a condition of things that may not or that has not occurred elsewhere. Human nature is the same everywhere, and we have been so fortunate heretofore in avoiding any unpleasant differences which pointed towards bloodshed, that we hoped all animosities had been settled in the determination to develop our resources.

The Bodie affair will be regarded as an example of the lawless spirit which has been unjustly said to prevail in mining districts, and it would have been better for the future prospects of the community if both parties had yielded up their grievances to the peaceful settlement of the local government.

MR. BURCHARD, Director of the Mint, has issued a circular with a view to preparing statistics relative to the production and consumption of gold and silver, asking those employed in the arts and manufactures to furnish a statement showing their yearly or monthly average consumption of gold.

ACORN GRANARIES OF THE MIWOK INDIANS.

granary to store them in for winter. When the crop was good and they harvested more than they wished to carry to camp just then, with a forethought not common among barbarians they laid by the remainder on the spot. Selecting a tree which presented a couple of forks a few feet from the ground, but above the reach of wild animals, they laid a pole across, and on that as a foundation, wove a cylinder-shaped granary of willow wicker-work, three or four feet in diameter and twice as high, which they filled with acorns and covered with thatch. There they remained safe. As these were often miles from a village, the circumstances denote that they reposed no small confidence in each other's honesty. It goes near to refute altogether the frequent allegations that they are a nation of thieves. Now-a-days, they make most of their granaries close to camp, either right on the ground or elevated on top of some posts.

They are very fond of hare, and make comfortable robes of their skins. These are cut into narrow slits, dried in the sun, and then made into a wide warp by tying or sewing strings across at intervals of a few inches. Soap-root is used in the manufacture of a kind of glue, and the squaws make brushes of the fibrous matter encasing the bulb, with which they sweep out their wigwams. With millions of tall straight pines in the mountains the Mi-wok had no means of crossing rivers, except logs or clumsy rafts. All their bows and ar-

rows were bought of the upper mountaineers. White shell buttons, pierced in the center and strung together were used as money, rated at \$5 a yard; periwinkles at \$1 a yard.

Their chieftainship, such as it is, is hereditary when there is a son or brother of commanding influence, which is seldom; otherwise, he is thrust aside for another. The Chief is simply a master of ceremonies. When he decides to hold a dance in his village, he dispatches messengers to the neighboring rancherias, each bearing a string whereon is tied a number of knots. Every morning thereafter the invited Chief unties one of the knots, and when the last one is reached, men, women and children joyfully set forth for the dance.

Scarification and prolonged suction with the mouth are the staple methods of cure among their shamans or physicians, some of whom are women. In case of colds and rheumatism they apply California Balm of Gilead (*Picea grandis*) externally and internally. Stomachic affections are treated with a plaster of hot ashes and moist earth. The shaman's prerogative is that he must be paid in advance, usually fresh

GEORGIA GOLD MINES.—The Louisville Courier-Journal says the growth in the gold-mining interests of Georgia has been remarkable in the past few years, and the yield of hulsion now goes over \$1,000,000 per annum and is rapidly increasing. New mines are being constantly opened. Dr. Little, State Geologist, says that there are unoccupied mines enough to increase the yield to \$10,000,000 per annum, without exhausting the quartz in a generation.

RINDERPEST is spreading in Russian Poland.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

An Excursion over the Narrow-Gauge Railroad.

EDITORS PRESS:—Excursion parties are one of the safety valves for the pent-up spirits of our metropolis. Through the turmoil of money-getting strife, the distractions of politics, office work, the ennui of evening parties, theater and opera going, club meetings and the like, there comes to every inhabitant of this dusty city visions of broad fields and sunny mountain slopes, clear streams and dimpling valleys, bubbling springs and shady dells. These are the scenes, the originals from the master hand of nature. Copies and imitations of which old masterpieces we have on the canvas in studio and theater and mimic representations in garden, park and fountain. These, the expression of a bright sense and clear perception of the beautiful, satisfy our everyday longings, but from them, like cultured students of art, we sometimes escape and pay our devotions at the shrines of nature, the source of all true art.

One of the most enjoyable occasions of the season was the Sunday excursion of September 14th, to the Santa Cruz mountains, over the South Pacific railroad, a distance of 67 miles. From Alameda point the road leads over many miles of rich, level land but little above tide water, and destined in time to support a denser population than peopled the marshes around ancient Rome. Here beautiful villas will rise to enrich the landscape, never, we hope, to be despoiled by the Goths and Vandals of a barbarous nation, or crumble, to be finally exhumed by the mousing antiquarians of a strange civilization. Whirling over this tract we entered on the firmer lands of Santa Clara valley. Pleasant farm homes, approached by long shaded avenues, followed each other in rapid succession, pictures of quiet independence, with a background of mountain views, crisp and browned in the summer sun. Santa Clara, the realized dreamland of amateur florists and tree worshippers, was next reached, and we spun a happy three miles to aristocratic San Jose, where we were reinforced by another carload of pleasure seekers. The Union Gatling Band had enlivened the way with ringing strains of music, and with a delicious outburst of the Pinafore frenzy, we steamed against time over the road to Los Gatos, a happy little town in smiling possession of a charming valley. Here we followed a rapid down grade into a wooded canyon, starting with scanty oaks and changing to madroña, laurel, and finally a sprinkling of redwood. A stream wound along by the side of the track in a glorious tangle of thickets, the despair of prim gardeners and the pride of the canyon. Quiet pools, slyly suggesting trout, shabby huts and preposterous diggers, wretchedly frugal Chinaman, wood flumes, and a decayed flume of the old San Jose water works, old mountain trails and rugged rocks, a short tunnel, with numerous suspicious percussion-like echoes (?), were some of the things we saw in this shifting excursive kadeidoscope. Wright's station is a handful of houses jammed in between aggressive mountain heights. A shaded stream runs through, and wildness reigns on all sides. Mine host spread an ample repast, and enlivened appetites made war on the hapless viands. Tables in the neighboring grove were spread with lunches from town, and peaches and watermelons fulfilled their destiny. Fun and frolic ruled the hour, music resumed, and dancing commenced. The big tunnel near by was visited; it is 6,200 feet long, and with the 1,600 feet to be completed. An interval of 25 miles of the richest scenery will bring one to Santa Cruz, the Mecca of fashionable pilgrims. The road will be completed by January 1st, and cannot fail of the immense popularity it deserves.

Among the excursionists we noticed Mr. Frank Morton, an experienced railroad man, and W. H. Thompson, an expert accountant, both now in the employ of the South Pacific Coast Railroad Company.

H. E. HALLETT.

Heating by Radiation.

Mr. Leeds, in the *Plumber and Sanitary Engineer*, advocates imitating the radiant heat of the sun in our dwellings. The whole warmth upon the surface of the earth is received by radiation from the sun. The air is warmed by coming in contact with the warmed earth. The air warmed by this contact with the heated earth rises, and the colder air from above tumbles down to take its place. This forms the great natural ventilation or circulation of air over the surface of the earth, which sustains all life.

For healthfulness, the open fire most nearly imitates the radiant heat of the sun. The air, warmed by immediate contact with the fire, is carried up the chimney. The radiation from the fire passes through the pure air without warming it, but warms any person or objects within range of that radiation, the air remaining cool and invigorating. All those hot-air contrivances, by which the air becomes hotter than the solid objects in the room, are unnatural.

The Jordan Mine, Mono Co.

In a late issue of the *Mammoth City Herald*, the Jordan mine is described as the most important discovery in Lake district, Mono county, California. The discovery was made but a few weeks ago, lying just west of the Mammoth croppings, and about on a line with the latter's upper tunnel. The discovery has attracted no little attention in the district, and the day after the character and extent of the find became known, and the value of the ore tested, the Jordan sprang at once into the front rank of Lake district properties. The Jordan is the second oldest location in the district, it being preceded only by the Alpha. It was located in August, 1877, by J. C. Brown and Alfred Jordan, but is now owned by J. C. Brown, F. D. Nichol of Virginia City, Z. W. Taylor and others. It is not yet incorporated, but doubtless will be, now that the value of the mine is fairly demonstrated.

Mr. Brown began work on the Jordan early in June of this year. A small shaft was started about 100 feet below and to the westward of the main bunch of croppings. This was sunk about 20 feet through the surface debris, and finally passed four or five feet through conglomerate, when it struck into a stratum of basalt mixed with porphyry and syenite. At a distance of 30 feet stringers of low-grade quartz began to make in, which gave the boys encouragement to keep on. A few feet further down, and Mr. Brown suddenly struck into a white clay gouge, dipping at an angle of 50° to the southward and eastward. Six or eight inches of this and the pick went into the ledge of the most beautiful quartz yet found in the camp. For the first three feet this quartz is solid, compact and fairly alive with metal, assaying from \$35 to \$350 a ton.

Then it became slightly broken for two feet and mixed with strata of talc, but it again comes in strong and continues so the remainder of the width of the vein, which is well defined by a reddish clay streak which carries gold in considerable quantities. From the red clay streak which defines the footwall to the white clay gouge of the hanging wall, is a distance of about eight feet, and from the pitch of the red clay it is seen that the ledge widens as it goes down. It is evident that in sinking the shaft the very apex of the ore body was hit, and that too at a point where nobody expected it.

The purpose of the owners is now to continue the shaft through the ledge and on down 50 or 60 feet further, then crosscut and test the ore at that depth. It is believed that it will there be found wider and richer than above. To this end the shaft has been enlarged, making it a double compartment, and better working facilities have been provided.

It is the northern extension of the Alpha, in the tunnel of which the same character of vein has been cut, and precisely the same quality of quartz found, only, of course, being cut at a much greater depth the vein in the latter mine is much wider, and the peculiarities of the ore more pronounced. In the Alpha occurs the same clay gouge, the same strata of talc, and the same reddish clay marking the footwall. All this proves conclusively that the ledge is the same in both mines, and that it is one of the most, if not the most important ledge in the district. The following is the result of an assay of four average specimens of rock taken by a *Herald* representative from the bottom of the shaft on the occasion of a recent visit: No. 1 (from next white clay), gold, \$21; silver, \$336.40. No. 2 (inner edge of rich streak), gold, trace; silver, \$216. No. 3 (quartz mixed with talc), gold, none; silver, \$55. No. 4 (streak next red clay), gold, \$41; silver, \$62.10.

New Mining District in Utah.

A correspondent writing from Hoosier Lake, Iron county, Utah, to the *Salt Lake Tribune*, announces the formation of a new mining district, to be known as the Hoosier Lake mining district.

The first piece of ore from this region was found three years ago, and assayed \$900 per ton (it was float.) Prospecting has been continued from time to time from then until now, with varying success. Within the last 30 days some veins and deposits have been found and located by parties of prospectors from Panguitch Fish Lake and other places. The ores found are gold and silver and copper, and are considered by old prospectors to be first-class, and will assay into the hundreds. The formation of the country rock is granite, quartz and porphyry. Specimens have been sent to different assayers, chiefly milling ores. Returns have not yet been received. The ledges, or veins and deposits, so far as prospected, are from 2 to 12 feet in width, carrying all the colors of chloride, ruby and horn silver, which so readily excite the miner. This is one of the most beautiful regions for mining purposes, in the summer, that any miner ever set foot in. Charming little valleys, with plenty of grass and spring water, surrounded by hills covered with a dense growth of timber, all within a few hours' ride from Panguitch Fish Lake, a splendid sheet of fresh water, where the mountain trout do most abound, and angling is real sport. There are quite a number of pleasure-seekers raticating at the lake, many of whom spend a portion of their time prospecting for rich ores.

Compressed Fuel.

It appears, from the London *Mining Journal*, that slack from coal mines is used to a great extent in France, by being compressed into brick fuel, which is extensively used in the French navy, and considered superior to the English compressed fuel. For steam vessels it has many advantages over coal, whilst a given tonnage occupies much less room than the same weight of coal.

Some important improvements, it may be stated, have recently been made in the manufacture of patent or compressed fuel, by briquette machinery, similar, but superior, to that for a considerable time in use in France, by which the material can be cheaply produced, so that the consumption of it should be considerably larger than it has yet been. Indeed, there should be no difficulty in manufacturing an article from slack alike suitable for steamships, manufacturers, and for household purposes, at a price much lower than that now paid for either hard or soft coal. This will be apparent from the almost nominal charge now made for slack, from which large quantities of excellent coke are made.

In France, in connection with the navy, both coal and patent fuel have been tried against each other, and the Minister of Marine has found the latter to be most advantageous in comparison with either Cardiff or Newcastle coal. He states that a better fuel was produced in briquettes, whilst there were the still further advantages of greater facility in loading, stowage of a larger quantity, diminution of loss from dust, and capacity to bear exposure. Consequently, the compressed fuel was generally adopted in the French navy. The best coal for the purpose is that of the Anzin mines, in the north of France. The Anzin Company, one of the largest working the coal in the northern basin, has a compressed fuel factory, with 4 revolvers and 2 Middleton presses at St. Vaast, where about 500 tons a day are turned out. The produce is absorbed by the French navy.

The Aniche mines, in the same direction, are also very extensive, and in connection with them are the Lomaine Patent Fuel Works. The material worked up is from 70,000 to 80,000 tons of small coal, and 5,000 to 6,000 tons of English pitch. The works make nearly 250 tons of fuel in 24 hours, and comprise a steam-engine of 50-horse power, three boilers of 45-horse power each, measuring machine for the pitch and coal, two washing machines on Bernard's system, a Carr's disintegrator, a centrifugal drying machine for molding the fuel on a system devised especially for the work by one of the directors and partners, M. Bourriez. The compression is obtained by the motion of a piston on a rectangular mold, which is constantly fed by a mixture of the small coal and pitch in a soft or pasty state, so that there is constantly produced a continuous and a solid band of fuel. Outside the mold the material is separated at each stroke of the piston into rectangular blocks, which are then completed and ready for loading into the wagons. Most of the fuel made is for the French navy. For carrying on the necessary work about 50 workmen are employed. The same company have three other factories, at Erquelinee, Hasard, and Marchiennes-au-Pont; so that the annual production of the various establishments is upwards of 300,000 tons a year, nearly the whole of which is consumed inside French territory. This, we believe, is more than is produced by all the makers in England, despite the vast quantity of small coal that is made, and the almost nominal price it is sold at. But there are several other factories in France for the manufacture of compressed fuel besides those enumerated, one of these being in connection with the Bethune mines, established near to the wharf from which the coal is shipped, and produces from 18,000 to 20,000 tons a year.

It will be seen that the manufacture of compressed fuel has become an important industry in France, not only being largely used by the navy in preference to the best steam coal, but for household and other purposes as well.

But one of the principal drawbacks to the patent fuel has been the heavy percentage of clinker and ash it has left after burning. But by a judicious selection of small coal, and having it cleaned and washed, there is very little doubt but that it would meet all the requirements of the Admiralty, as well as of steam consumers generally, for it has been admitted by the dockyard authorities to have some important advantages, for in their report they say: "We think the patent fuel would resist deterioration when exposed to the weather much better than ordinary coal, and on this account might be found specially suitable for shipment to the foreign coal depots, and that without difficulty it might be secured of a caloric value nearly, if not quite, equal to the best steam coal now supplied."

FIRE-DAMP DETECTOR.—Prof. Forbes before the recent meeting of the British Association reported that the committee in charge had constructed two instruments for detecting fire-damp, the principle in the construction being founded upon the fact that sound traveled quicker in light gases than in dense ones, indicator was able to detect. Some alterations were recommended in the instrument, and the committee added an opinion that it would be very useful in ensuring the safety of mines.

Santa Fe.

Governor Amey, of New Mexico, speaking of Santa Fe, says:

The city of Santa Fe stands upon both sides of Santa Fe creek, a small river heading in the lake on the top of the mountain 12 miles to the east, and running westerly into the Rio Grande del Norte, 14 miles from the city. From it the fields and gardens in the valley are irrigated for cultivation, the whole volume of water being usually, during the irrigating season, diverted into the branching acequias or irrigating canals. The city residences and other buildings are almost universally of the Mexican style, built of adobes or sun-dried brick, one story high, are warm in winter, and cool in summer, and are, withal, quite comfortable. It has been aptly said that the city, when viewed from either of the fine natural eminences overlooking it, presents the appearance of a large collection of brick kilns. Huge spurs of the Rocky mountains rise in the immediate vicinity of the northeast, the east and the southeast, and loom in the distance to the northwest, the west and the southwest, a series of low table-lands lying to the north, the whole presenting an interesting landscape. Situated at an elevation of 6,862 feet above the sea level, the climate is very agreeable, the atmosphere very rare and pure, and the salubrity of the place unsurpassed. It enjoys, on this account, a widespread and very enviable reputation. The population is now not less than 6,500. Of these, fully 5,500 are persons of Spanish or Mexican descent, speaking the Spanish language, the balance being wholly American and Europeans—the entire population being conventionally divided into two classes, the "Mexican," or Spanish-speaking, and "American," or English-speaking people, the latter class being composed, really, of a majority of foreign-born persons, among them a large proportion of Jews.

The plaza, or public square, in this city, north of the river, comprising an area of about two and a half acres, contains, enclosed with railings, inside the streets, a beautiful park of trees, covering a space of about an acre and a quarter. The trees are mainly cottonwood, the eight large ones forming the entire north tier having been set out in the spring of 1844 by Mariano Martinez, the Governor of New Mexico, and others in 1863 at the private expense of the citizens. The plaza is surrounded on the east, south and west sides with good adobe buildings, the principal mercantile and other business houses of the city, and on the other side stands the old "Palace," containing now the Governor's mansion, the United States Designated depository, the United States and Territorial court rooms, the Legislative hall, the Territorial library, and the Territorial Attorney-General's office.

It is contended that Santa Fe is really the oldest-settled town upon the whole territory of the United States. As the city of Mexico today is but the Aztec pueblo of Tenochtitlan of Montezuma, so is Santa Fe but the old pueblo of Cicuye of Coronado. Santa Augustine, in the State of Florida, settled in 1565, was conceded the distinction of being the oldest until the acquisition of New Mexico and its capital, Santa Fe, by the treaty of Guadalupe Hidalgo, in 1848, when the latter assumed that rank by virtue of being, when the Spaniards first visited it, in or about the year 1542, a populous, regulated Indian pueblo or town—one that had been in existence there is no knowing how many decades or how many centuries.

Big Blue Lead in Nevada.

The *Gold Hill News*, under the heading of "Gravel Gold Mining," says that the "Centennial," a new mine, is right on the track or channel of the old blue lead. The exhausting of shallow placers in California led to deep mining, worked by hydraulic process, long tunnels, and deep shafts. Thus it was that by degree the great ancient river channel, better known as the "Big Blue lead," was developed and traced from north to south throughout the gold region. This famous lead contains some of the richest and most permanent of the gravel gold mines of California at the present time; mines that will last for many long years to come.

The Centennial is situated in Washington township, Nevada county, California, 14 miles above Nevada City, in a range of hills at the head of Jefferson ravine, between the South Yuba river and Deer creek. It comprises a tract of heavily-timbered land 800 acres in extent. The mine has been considerably prospected under the superintendency of Major Downie by about 3,000 feet of tunnel, developing some very good gravel streaks carrying heavy wash gold, as well as by shafts, and the dip of the gravel having been obtained, a prospecting tunnel to the eastward is now being run, in order to ascertain the best and most advantageous point to start a main working tunnel directly into the gravel deposit, low enough to secure the best possible drainage. A strong, permanent stream of pure, cold water, of 12 or 15 miners' inches, flows from the old tunnel, and is, without doubt, from the great channel or river itself. This stream will prove of great value and importance in the gravel washing. The great "Blue Lead," which has been traced for hundreds of miles, has already given to the world over \$300,000,000, and now yields \$10,000,000 annually; consequently the chances for the Centennial turning out rich by and by are pretty well assured.

MECHANICAL PROGRESS.

Terrestrial Magnetism and Electricity.

Prof. Ayrton and Perry, of the College of Engineering, Tokio, Japan, communicate to the *Philosophical Magazine* a short note, proposing the hypothesis that the phenomena of earth currents, terrestrial magnetism, and atmospheric electricity are due to the fact that the earth is an electrified condenser, whose capacity or potential is continually changing on account of its rotation and annual orbital motion, the successive cooling and warming of the air, the formation of clouds and rain, etc., etc. These changes produce electric currents tending always to restore the equilibrium, whose flow the phenomena in question. They suggest that observations of atmospheric electricity may be used to predict atmospheric changes.

William Leroy Brown describes, in *Nature*, a new lecture experiment, to show the action of terrestrial magnetism. A rectangular frame of light wood, carrying 20 coils of insulated wire, was suspended in a horizontal position from the pans of a balance, so that the long sides of the rectangle were at right angles to the beam; and mercury connections were arranged at the middle of the short sides, so that a current could be sent through the wire. This apparatus being placed with the long sides of the rectangle perpendicular to the magnetic meridian, when the battery current passed from east to west on the northern side, and from west to east on the southern side, the north side would be attracted and the south side repelled by the earth currents, both influences combining to deflect the beam of the balance. On reversing the current the deflection was in the opposite direction.

It would seem from the above, which we clip from a late *Scientific American*, that this proposed hypothesis of Prof. Ayrton and Perry and the mechanical contrivances of W. Leroy Brown described, are new discoveries. The fact is both are old, substantially the same machine having been used for a long time by Prof. Neri, of St. Ignatius College, San Francisco to solve the phenomena mentioned in the above hypothesis, which is not strictly a hypothesis.

A WONDERFUL GAS MACHINE.—Mr. J. T. Guthrie, of Leesburg, Ohio, is said to have recently patented a machine for utilizing the gas from bituminous coal that is otherwise lost with the smoke through the flues and chimneys. The machine is very simple, and can be attached to a common cooking or heating stove; and the advantages claimed for it over all previous inventions are such as to render it one of the greatest improvements of the age. Any person can handle it easily, and the same fuel that cooks your breakfast, will produce an abundance of pure gas, sufficient to illuminate your house during the night, without any expense whatever. Mr. Guthrie also claims the right of attaching it to furnaces, grates and any and all places where coal is used for fuel and heating purposes. It is said that Mr. Guthrie has proposed to the Cincinnati Exposition Commissioners to light the entire Exposition building with as good and pure a quality of gas as can be produced in the city gas works, and this by using the same fuel that heats the boilers of their power engine, without the cost of one cent for the fuel. This invention is in successful operation in Leesburg; and the inventor is visited daily by hundreds of people to see the wonderful machine. All, so far, bear testimony to its wonderful merits and general utility. The inventor claims that good, pure gas can be produced by the machine at a cost not to exceed 20 cents per 1,000 cubic feet, and earnestly invites practical men from all parts of the country to come, see and examine the workings of his invention.—*American Manufacturer*.

NEW POLYGRAPH.—The latest method for the rapid reproduction of letters, drawings, etc., has been brought out in France, and is made as follows: A plastic mixture, composed of 500 parts (by weight) of white gelatine, 500 parts of glycerine, 50 parts of glucose, 50 parts of white glue, and 350 parts of water, is poured hot into a shallow tin box of suitable size. The ink used for writing or drawing is made by adding to a suitable quantity of water 20 grams of violet aniline and 300 drops of alcohol. The ink is allowed to dry on the paper, which may be of an ordinary quality, and then the written side is laid on the plastic paste and is gently pressed on with the hand. After waiting for a minute the paper is neatly raised, and the writing will be found to have been transferred to the surface of the paste. From this as many as 50 copies can be taken without the aid of the press. What is left of this ink is carefully washed off by means of a warm sponge.

AMERICAN ELEVATORS IN FRANCE.—It is now proposed to introduce American grain elevators into use in the port of Havre, a committee, composed largely of American residents in France, having been recently formed for this purpose. It is curious that so important a seaport as Havre, where enormous quantities of grain are received annually, should be destitute of the simple and well-known method of handling grain, such as is afforded by the elevator, but this is the fact, the only mode of transfer being the primitive one of carrying on men's backs, and the grain is left in heaps upon the quays, exposed to loss by weather and by theft.

DEVICE FOR COMMUNICATING BETWEEN ENGINE AND CARS.—An English journal notes the exhibition by Mr. T. T. Powell, Harrogate, of a working model of railway train, line and signal cabins, showing the operation of his appliances for securing direct and interchangeable communication between passengers, guard, driver and signalmen whilst the train is running. The invention consists of a light insulated metal rail or bar placed in the center of the four-foot way, extending from one block station to another, and united to these stations by insulated wires in connection with batteries and instruments placed in the signal cabin, the station master's room or any other convenient place. In combination with the insulated rail a trailing runner or drag is placed under the engine and guard's van, constructed in such a manner as to be in constant contact with the insulated rail, and connected with batteries and speaking or signaling instruments upon the engine and in the van. By these means the signalmen, guards and drivers will be enabled to communicate interchangeably with one another and with the station at each end of the block. This appliance not only gives these unusual facilities to the officials, but affords the same privileges and safety to passengers. This is accomplished by fixing under each carriage a suspending runner or drag with a direct and easy communication from the inside of the passengers compartment by a connecting cord. In case of danger of alarm, the passenger, by pulling this connecting cord, at once releases the runner, which falls upon the insulated rail or bar and immediately gives the alarm to driver, guard and the two signalmen at either end of the block within which the train is running. The system can be easily and effectively applied where the present block system is in use.

FLEXIBLE LINING FOR COAL-OIL LAMPS.—An ingenious invention has recently been introduced in Maryland to ensure safety in the use of coal-oil lamps. It consists of a lining made of flexible material, which prevents the lamp becoming foul by the expansion of the material of the lamp, permitting oil to exude and soil the band, or whatever it may touch. A broken lamp becomes harmless, as there is neither gas from the oil nor oil itself to spread destruction to everything it comes in contact with. Careless handling will not bring the oil in contact with a hot lamp. The lining is a natural receptacle for fluids, a non-conductor of heat, and is improved in several essentials by being filled with oil. It is strong enough to resist rupture from much rougher handling than can be expected from an article designed for this purpose. No change is necessary in lamps now in use. The attachment is made to fit any coal-oil lamp. An accommodating coupling, or joint, enables any one to change their lamp from a foul and dangerous to a perfectly safe, clean and harmless light.

MEASURING DISTANCE TO REMOTE OBJECTS.—The desirability of some convenient and reliable means for measuring distance to a remote object, has set several ingenious people to work to invent an instrument for that purpose. Mr. John Boger, of Powhatan Point, Belmont county, O., has recently patented an improved instrument that promises to effect this object. The invention is based upon the general principle of the employment of two right angular bars, one of which is provided with a sighting glass, and is directed toward the object, and the other graduated and provided with another instrument, which, when adjusted to a certain position upon this bar and turned to the object, indicates by the angle at such position the distances which the different angles and positions together indicated, being previously determined by careful measurement.

A NEW STEAM BOILER.—An English engineer named Whitesad, recently exhibited at Owleston, near Sheffield, a boiler made on a new plan. In making this boiler a ring of steel is cast and heated. Then it is placed upon a large roller, and by the aid of smaller rollers it is enlarged to the requisite dimensions. The ring is run from one end of the roller to the other, and is returned by reversing the machinery. The other portions necessary for the completion of the boiler are subsequently put on with bolts. The machinery is rather expensive, and it is its cost which is said to be the point upon which the success of the invention hinges. The inventor claims that within six hours he can construct the shell of a boiler of a more durable nature than those now used.

AUTOMATIC ENGINE.—A new automatic pumping engine is in operation at the Providence (R. I.) water works. It has 10 cylinders, five for water and five for steam, arranged alternately in a circle. It possesses an enormous capacity, but it will, without attention from the attendant, do the duty of pumping either for a single faucet or for a dozen steam fire engines. The cylinders are all connected to a single central upright shaft, which automatically either makes one revolution in five minutes or 25 in one minute, according to water required. If the fire burns low, the engine will open the damper; if this is not sufficient, it will put on the blower.

THERMOMETER PLATE STAMPING.—Messrs. Robison & Burr, machinists and founders, of Champaign, Ill., have recently completed a very intricate machine for graduating and stamping thermometer plates. The machine stamps the figures from 40° below zero to 280° above, makes the long and short marks, and has a range from 30° to three-eighths of an inch to 30° in an inch. It will make four gross of plates per day.

SCIENTIFIC PROGRESS.

Rusting of Iron.

Dr. J. Treumaan, of the Haaover Technical High School, says, in *Iron*, that the phenomenon of rusting, was, to within a very recent period, commonly explained in the following way: Iron, covered with a thin layer of water, and exposed to the influence of atmospheric air, is changed on its outer surface into hydrated peroxide by taking up the oxygen dissolved from the air by this water, and then forming an oxide of iron, which combined chemically with one part of this water. But a few years ago, Calvert proved that, besides oxygen and water, the carbonic acid, always present in the atmosphere, was an essential factor in the process of rusting. He showed, also, that a proto-carbonate of iron was an essential element of iron rust, and instituted a carefully conducted series of experiments, which resulted in proving that iron rusts most easily in a mixture of damp carbonic acid and oxygen; that, contrariwise, it does not rust when exposed either to perfectly dry carbonic acid and oxygen, or to damp carbonic acid, or to damp oxygen. Iron exposed to the influence of pure oxygen does not rust, so far as Calvert's experiments go. If part of a bar of iron be dipped into water below oxygen, this part becomes covered with hydrated peroxide. The hydrogen found in the upper part of the vessel, which was at first full of oxygen, only justifies the conclusion that this oxide of iron originates in the decomposition of this water, effected by electrolysis. In iron are constantly present small quantities of other metals, and to these must be attributed the creation of electric currents, which first decompose the water and then rust the iron.

Rusting is therefore in all cases to be attributed to the simultaneous action of carbonic acid, water and oxygen, as well as under certain circumstances, decomposition of the water occasioned by the presence of metallic impurities in iron.

The beginning of the action of rusting is accelerated where the damp air to which iron is exposed contains small quantities of sulphuretted hydrogen, the latter causing the formation of sulphides of iron, which is presently converted by oxidation into a proto-sulphate. Small quantities of chlorine, muriatic acid or acetic acid favor the formation of rust.

That iron which is exposed to the influence of water containing salts, and especially water which contains solutions of chlorides compounds, especially chloride of magnesium, chloride of sodium, ammonium chloride, potassium chloride, barium chloride, calcium chloride, rusts in a very energetic manner as soon as atmospheric air is admitted to it, is a fact which has been lately corroborated over again by A. Wagner, whose experiments are detailed in Dingler's *Polytechnisches Journal*. This observation deserves the greater attention from the fact that the benefit derived by purifying the feed-water of steam boilers from sulphate of lime by means of barium chloride may be completely neutralized by the presence of compounds of chlorine which corrode the boiler plate.

The smoother the surface of the iron the slower does rusting go on. Rust always makes its first appearance in fissures and crevices filled with hammer scale and spreads itself in all directions from those parts first affected. The differences in the formation of rust exhibited by the various kinds of iron are remarkable. Hard foundry pig, richest in carbon, resists oxidation the longest; pure iron, poor in carbon, rusts very quickly under parallel conditions.

The fact has often been proved by experiment, that iron does not rust if it lies under water containing small quantities of potassium, soda carbonate, lime, ammonia, or borax. Iron can also be protected from rust by means of solutions of potash or soda. The protection granted by these agents will last for months, if a certain measure of dilution is not exceeded; but ceases when these solutions have become completely saturated with carbonic acid. The latter circumstance seems to warrant the assumption that the effectiveness of these agencies is attributable to the property of free alkalies, themselves containing carbonic acid, to enter into chemical combination with this body, and thus to prevent it from acting on the iron. Practically this principle is made use of principally for the protection of boilers which have to lie idle. They are filled with milk of lime, or solutions of soda are used, with the object of the prevention of rust. Of course, this protective solution must be renewed from time to time, since, when saturated with carbonic acid it loses its virtue.

FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—At Montpellier, on the 28th of August, the annual congress of the Association for the Advancement of Science was opened. The President (M. Bardoux), in the course of his inaugural address, pointed out that the modes of teaching should follow the developments and modern society, and that the old method, in which memory played the principal part, should be abandoned. What was now required was a system of instruction which developed the judgment and set it on its guard against chimeras, without extinguishing the cultivation of the beautiful. This was the urgent reform which secondary instruction needed.

Chemical Denudation.

T. Mellard Reade, in his book on "Chemical Denudation in Relation to Geological Time," says:

The phenomena of sub-aerial denudation now holds an important place in geological theory, and the changes of contour and surface which were formerly attributed to subaqueous influences have come to be chiefly ascribed to the action of glaciers and torrents. In this main, there is no doubt the second thought of the geologists are the most accurate; but the action they have in view is mostly mechanical, and the chemical action of acids held in solution by the rain or in the atmosphere has not been so much taken into account. In fact, although the amount of mechanical denudation by rain has been carefully estimated, and computations of time founded upon it, no attempt has, up to the present time, been made to estimate the soluble constituents annually removed from the earth's crust.

This the author of the present treatise essays. Without following him through his calculations a few of the results may be stated. He considers there is ground for the provisional assumption that the effect of soluble denudation by rain in England is to lower the surface about a foot in 13,000 years. Then, as to the bearings of these changes on the question of geological time, he shows that, by even a much lower estimate of the rate of denudation, it would take 25 millions of years to accumulate the quantity of sulphate of lime and magnesia contained in sea water, and 200 millions of years to renew its chlorides; and on these and other grounds that the sedimentary crust of the earth, taken on an average at 10 miles thickness throughout, must have taken, in laying down, on a very moderate estimate, 600 millions of years—a period, by the way, amply sufficient for all the changes of the evolutionists.

BLOWING-OFF STEAM BOILERS.—A French essay has the following on blowing off steam boilers: Those who possess externally-fired boilers, working only by day, have all observed that the fire being covered by night, and the doors closed, the pressure rises during the night, often sufficient to open the valves. This shows that the masonry, being at a much higher temperature than the boiler which it envelops, imparts to it some of its heat. The same effect of heating the boilers is produced, to a less degree it is true, but nevertheless to some extent on the outer jacket of internally-fired boilers. It is consequently injurious to empty boilers soon after having stopped them, because after emptying, the plates would be heated by the action of the masonry. It is well to admit a current of air through the flues some hours after the stoppage of the generator, and not to empty it before the flues become cooled to a temperature below 150°. When the flues are not too hot, no serious inconveniences are experienced in emptying the boiler under pressure. We do not say at high pressure, as for a boiler the pressure of which would be 5 kilograms, the temperature of the water being 152°, a greater quantity of steam would be generated during the process of emptying; we think that at a pressure of one kilogram, the boiler could very well be emptied. In internally-fired boilers, as there is no masonry to cool in the furnace tubes, it would be well to admit the current of air intended to cool the masonry behind the boiler, as in this case the furnaces would be cooled more rapidly than the jacket. We have sometimes seen owners empty their boilers almost immediately after the fires have been extinguished, clean them with cold water as soon as they were empty, and keep up a current of water so that this workmen might work there. Boilers of small dimensions sometimes resist treatment, but in large boilers it will be seen that unequal contractions must take place, which bursts the rivets.

MICROMETRIC.—Apropos of the forthcoming meeting of the microscopists, Mr. G. Fasoldt, an optician of Albany, some time ago announced to the scientific world that he was able to manufacture a microscopic slide, called "Micrometric rulings," in which, by the aid of a diamond, he had cut 120,000 clearly defined lines to the inch. This seemed an impossibility, and microscopists in this country and Europe obtained specimens mainly for the purpose of proving the falsity of the statement. Several were able to see 45,000 lines, the rest being invisible to them. Fasoldt's son said he had seen 90,000 of the lines, but serious persons declared he imagined all above 45,000. Dr. Reznor of Cleveland, a gentleman of great scientific ability and labors, has discovered a method of so illuminating the rulings that they are easily read. On Monday last, Dr. L. Younghusand, of Detroit, visited Dr. Reznor at his office in Cleveland, and there saw the wonderful sight of 120,000 lines to the inch, by the aid of Zantmayer's microscope and Spencer's one-sixth objective. Present at this examination was Dr. Dutton, an eminent physician, who also saw them. Dr. Younghusand regards this slide of Fasoldt's with Dr. Reznor's illuminator, as one of the greatest wonders of the age, and one which will enable the faithful students and workers in microscopy to accomplish still greater victories in their department of science.—*Buffalo Courier*.

The Mining Share Market.

The general condition of the share market for the week has been that of a dismantled ship, buffeted about helplessly upon the waves. There has been very little interest manifested in the stock business. Fluctuations were constant, but transactions very slight. News from the flooded mines was favorable, but fell upon a dull and listless market. Bodies were slack, and showed no sign of recuperation. A general demoralization has existed, which manipulators could not stay even by news of ore in the Union shaft. Comstock's declined, but towards the end of the week particular favorites, such as Ophir, and Eureka Con., gained perceptibly. Operators have been on hand for many days waiting for a turn in the tide towards improvement, but are still waiting. All stocks were in light demand, and up to the time of writing (Thursday, 3 P. M.) there are no indications of any kind of a "boom" in the market.

Gold-bearing Soapstone.

We learn from the Nevada City *Transcript* of the 30th ult., that the proprietors of the Stockbridge Soapstone and Asbestos Company, whose quarries are located on Bear river, 18 miles southeast of Nevada City, have for the past year been engaged in extracting soapstone, until they have accumulated thousands of tons of waste, that has been dumped down the mountain side. This waste was supposed to be utterly worthless until recently, when the attention of the workmen was called to an old arastra that had been standing in the locality for 20 years or more. Supposing that the played-out machine must have been fed on rock that was found thereabouts, they crushed several small quantities of the waste soapstone, a few days since, and found that it was rich in sulphurets. A number of tests of the stone have since been made, and it is found to pay from \$10 to \$40 per ton. The gold does not lie in pockets, but is to be found throughout the whole mass. It is the intention of the company to at once erect a mill on the grounds and commence taking out the gold. There will be no expense incurred in sinking shafts or running tunnels, as the material is taken out from the same quarry that the company have heretofore been taking soapstone for lining furnaces.

It is a little remarkable that material containing so large a percentage of sulphur should be appropriate for furnace lining. Soapstone, or steatite, is a common mineral, and constitutes extensive beds in some regions. It is often associated with serpentine and dolomite, and frequently contains crystals of dolomite, asbestos, tourmaline, magnetite, etc. It is the material of many pseudomorphs, the most common being pyroxene, hornblende, mica, etc. Steatite is a compact form of talc, and is an impure hydrated silicate of magnesia.

DE GROOT, BIRGE & Co., mining engineers and assayers, is the firm style adopted by Messrs. Henry De Groot, Sr., F. E. Birge and Henry De Groot, Jr., carrying on the above business in this city. The senior member of this firm is well and widely known throughout California, and the mining districts of the interior, being one of the most competent and reliable mining experts on the Pacific coast, where his experience in this capacity covers a period of more than 30 years. Mr. F. E. Birge is a wide awake young man favorably known in this city for the past 18 months, who came here with complimentary letters to some of our best people from their friends in the East. Being a young man of fine character, good habits and thorough business training, he will not fail to meet with appreciation and success. Henry De Groot, Jr., is the son of the senior member of the firm, and a careful and practical assayer and metallurgist, well known through his connection with various quartz and copper mining enterprises in California. With such a lengthened experience, and so large a share of working talents, this firm will be likely to receive, as they well deserve, a liberal patronage in their line of business.

THE importations of gold and silver at the port of New York from Aug. 1st to Sept. 12th amounts to \$20,290,187, of which quantity \$19,650,763 was gold and 639,424 was silver. Of the total amount imported \$10,030,846 arrived during the week ended Sept. 12th.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

IRMS.—Ledger, Sept. 27: The shaft of the Good Hope is now retimbered to the water line, some 35 or 40 ft from the surface. There are 500 tons of ore on the dump. The Empire company at Plymouth are sinking the south shaft 100 ft deeper to enable them to take rock from the 1200 level.

BUTTE.

DUOTOWN GOLD.—Mercury, Sept. 26: Five men are employed in working the Baden mine. The owner, G. W. Cummings, showed \$480 as the result of 72 hours' run on the claim. The force has been kept busy for several months back in placing the property in working order. This task was completed last week, and active operations in extracting the precious metal were promptly begun.

ARMSTRONG MINE.—From M. N. Randall, superintendent of the Armstrong mine, located at Boston ranch, we ascertain Wednesday that the work of developing the property is progressing satisfactorily. Thus far the rock has been prospecting well. A second and lower tunnel is now being run, and the management expect to be taking out paying rock in large quantities within a few weeks' time.

DEL NORTE.

MIXING NEWS.—The Crescent City *Courier* says: The Big Flat Gravel mining company are pushing work in a favorable manner, and have the completion almost in sight. The Mountaineers are at work every day on their Jones' Creek ditch, which presents a substantial appearance. The French Hill Gold mining company are carrying on a large work in the business men and supervisors seeing that an immense trade must flow from the mines in the most approved manner now known to hydraulic mining engineers.

FRESNO.

RICH DISCOVERIES.—Republican: During the present summer many gold and silver-bearing ledges have been discovered in the eastern portion of Fresno county. Some of these veins are of immense size, and are exceedingly rich. One of them, situated in the same immense belt, is thought to be a continuation of the Comstock, and bids fair to equal that famous lode, both in extent and richness of its ore deposits. On the business men and supervisors seeing that an immense trade must flow from the mines to some convenient point on the railroad, have taken steps to build a road and secure the prize for Fresno.

INYO.

MONOCK.—Independent, Sept. 27: On the 19th instant crosscut in No. 2, in north drift 300 paces, run through the ore vein in main drift at a width of over 4 ft. In a few ft the crosscut passed through the second vein as found in crosscut No. 1. At present writing face is in ledge-matter and ore. Ground at this point looks very favorable for yielding a large amount of ore. Started a crosscut east from drift north, 500 paces, this morning, at a point in drift 200 from here in main tunnel. Have good ground for ore at this place. The under air-drum to 800 ledge is making good progress, and carrying fine ventilation with it.

INDEPENDENCE TUNNEL.—A blind ledge, prospecting quite well, was cut a few days ago, and in a short distance further promising ledge belonging to the Sardinia company will be intersected at a depth of about 150 ft.

LASSEN.

ITEM.—The quartz claims on Gold Run, north side of Diamond mountain, are giving indications of great value. Some of them have already been bonded at a high figure.

MONO.

MILL CREEK.—Bodie News, Sept. 27: Parties just in from this newly-opened camp report matters there as encouraging in the extreme. Daily new discoveries are being made of rich gold-bearing rock, and the prospectors are in high spirits over the outlook. We were shown some pieces of rock taken from the ledges found there, which show magnificently in native gold. Most of the rock is not the free character of ore, but much found is susceptible of easy manipulation, being clear from base or refractory matter. The approach to the mineral-bearing country from Little Lake is rugged in the extreme—only a trail being now in use, over which pack animals travel with difficulty.

ITEM.—Workings on the various claims on the east side of Bodie bluff average all the way from prospect holes to shafts 80 and 100 ft deep. The veins now being worked at a depth have all an easterly pitch.

TOCAL.—Bodie Chronicle, Sept. 27: The shaft is down 625 ft, still in hard blasting rock. The Syndicate drift is in 457 ft and in good vein matter, the last 10 ft passing through several small stringers of very rich ore. The south lateral drift, on vein No. 3, has been advanced this week 17 ft. The ledge in face of drift is six ft wide, of good ore.

MCLINTON.—The west crosscut, 500 level, has been advanced 14 ft. The north drift has been advanced nine ft, the ledge being about 20 inches wide, with considerable improvement since last report. Drift on Bulwer ledge has been advanced 14 ft, the ledge showing a width of 18 inches. The east crosscut in new shaft has been run seven ft.

NOONDAY.—Fine developments are being made in crosscuts on 312 level. North drift is in 200 ft.

BODIE.—Machinery for the new air compressor is in position.

CHAMPION.—Winze down 75 ft, with a six-foot ledge of good ore in the bottom. About two and a half ft of ore are very rich, the balance being very good. In the winze struck a heavy flow of water, compelling a cessation of work in it.

BLACKHAWK.—The shaft is down 380 ft, the formation continuing of a coarse, black porphyry and quartz, showing a vein formation.

QUEEN BECK.—The west crosscut 250 level is in about 520 ft, is in stringers of good ore, which look favorable for a ledge near at hand. The upraise in north drift is up 15 ft in good milling ore.

SOUTH BELVIDERE.—The east crosscut on the 150 level has been advanced 10 ft during the week. A few days ago a ledge about 12 inches wide, of quartz and clay, was passed through. Some of the clay prospects well in gold. The crosscut will be continued for the purpose of cutting more ledges, which are known to exist in the ground of the company.

NEVADA.

QUAKER HILL.—Transcript, Sept. 23: The cement claim at Quaker Hill, owned by Messrs. A. Sargent, Geo. Jacobs and others, has become an assured success after about two years of indigible prospecting. Last June the claim was purchased by a syndicate of prospectors, and has since been going on. The channel has now been pushed through for a distance of 126 ft without the rim-rock opposite the shaft being reached. The bed of gravel is from 15 to 16 ft deep. The dirt is quite even all the way, paying from 25c to \$1 per pan. The prospecting shaft is too far removed from the channel to admit of convenient working, and a new one is to be sunk immediately at a point 300 ft southwest of it. Hoisting works and a 10-stamp cement mill are to be erected at once. The mine now ranks among the most promising ones in the country.

THE NEVADA CITY MINE.—The main drift of Messrs. Shoecraft & Sprague's mine (formerly the Schmidt claim), at a depth of 150 ft, is being pushed ahead steadily. A side-drift ground is being opened up preparatory to erecting a new mill. Not much ore will be regularly stoped out until the new mill is ready for it, but some extracted in running the drift paid over \$40 a ton, which is more than double the yield anticipated.

RICH WASH.—Twenty-three ounces of washed nuggets were taken from a few ft of gravel in Grisel & Wing's claim, Washington, in this county, last week, and brought to the Citizens Bank here.

YOC HET.—Grass Valley Union, Sept. 23: Hydraulic companies are taking advantage of the lack of water to put their claims in order for working the coming winter. Yuba quartz was crushed by the Yuba mill. At the Yuba Gold mine above Washington the manager, Mr. A. DeLand, has three shifts at work on a drift to cut the pay chute in the lower tunnel. The rock has been very hard since he began work, and only 12 ft had been run when Col. Rogers left there on Wednesday morning, at which time the rock drilled easier and it was thought better progress would be made. The wheel, flume and many things about the mill are sadly out of repair, and Col. Rogers has placed these in charge of Mr. Chas. Knowles, a practical mechanic.

IRMS.—Shultz & Co., who have been engaged in tunneling to strike the gravel ledge supposed to exist near the Greenhorn canyon, beyond Banner mountain, have struck some very good indications and they think they will be able to reach the main channel in about 10 days. The gravel channel, flume and many things about the mill are sadly out of repair, and Col. Rogers has placed these in charge of Mr. Chas. Knowles, a practical mechanic.

DEANES.—The reported rich strike in the Deane has been denied by the *Examiner*. The 27th inst. the Deane The extraordinary seal lately found in the Deane is supposed to extend northeast through the Marlow, Black, Hancy and Bishop mines, all of which are situated within a mile of the first named. Six years ago the Bishop produced \$8,000 within a distance of 30 ft. The Black claim, \$11,000 in 15 or 20 ft, the Hancy \$1,400 in 7 or 8 ft. The seal is said to have yielded several hundred dollars to the Deane, but the seal is said to have been \$100,000 extracted within the distance of a few ft. Some of the chunks of gold are reported to weigh as much as one.

IRONCLAD.—Transcript: The Ironclad mine at Rough and Ready continues to look well. A 10-stamp mill is to be erected as soon as possible. Mr. Cannet has made arrangements to put in a Willard blow-pipe furnace to facilitate the milling and reduction of ores.

THE SANTA ANITA LEAD.—The Santa Anita mining company, three miles above Washington, have been pushing their tunnel head steadily since the last report. At a distance of 220 ft from the mouth a ledge eight ft thick and pitching east has been developed. It is thought this is the main ledge. The two others opened up some time since pitch to the west and are much smaller. Seven men are kept at work, and about 150 tons of ore have been sent to McClellan's, will pay from \$12 to \$15 per ton is already on the dump. It is the intention of the company to get the mill erected and in operation before the snow flies. Twenty tons of ore can be easily extracted each day from this claim, after it is once fairly in working order. John McCarty is running a tunnel on the extension of the Santa Anita, south side of Poorman's creek, where he is believed to have a ledge some five ft thick. The grade of the ore is about the same as that mentioned above.

A PAYING ORAYEL CLAIM.—The bullion product of the Excelsior Water and Gravel mining company, at Smartsville, for August was \$51,640. The capital stock has recently been increased to 100,000 shares, and two dividends on the new stock have already been paid, each aggregating \$25,000. Another dividend of the same amount has been declared.

ITEM.—The Campbell brothers have recently struck a fine ledge in the reservoir at Chapman's ranch. The ore is said to be rich in sulphurets and gold.

RICH QUARTZ STRIKE.—Grass Valley Union, Sept. 30: A rich strike in quartz is said to have recently been made in a newly discovered ledge on Manzanita hill, about one-half mile east of Forest Springs school house. The parties who discovered the ledge have been working on the ground about three months, and have put down a shaft 26 ft, or as far as they could go at present on account of the water. The rock, dirt and cab all prospect richly in free gold, the quartz being hard and white and not decomposed. The ledge, which is known as the "Lone Tree," is an entirely new discovery, and has never before been worked. It was found by two prospectors who have been in the district about six months. The find is said to be creating some excitement in that portion of the district.

PLACER.

ITEMS.—Herald, Sept. 27: W. H. Puffer, of Penryn, has recently had a rock crushed at Pugh's mill, from the mine near Penryn, that panned out something over two ounces to the ton. Mr. Hooper, who has been working a ledge on Dutch ravine, recently made a crushing to the tune of over \$800 per ton. It is reported on reliable authority that Heenan and Lawler have recently struck some very fine rock in their shaft out near Rock creek.

SAN BERNARDINO.

NEW YORK DISTRICT.—The Pioche *Record* says that the New York district, in San Bernardino county, 5 miles from the Nevada line, has several good ledges of free milling ore which will average \$50 per ton. Assays have been made as high as \$800. A Mr. Macfarlane is removing a quartz mill from Long Valley, Nev., to this district at Ivanpah. Two mills are already running. The ore at Ivanpah appears to lie in deposits or pockets, many of them yielding exceedingly rich ore. There are rarely any seams or mineral stains to indicate the whereabouts of these pockets and the miners go blindly at their work, trusting to luck. A pocket containing a couple of tons of ore was struck, and which yielded \$3,000 per ton. Fifty dollars per ton is charged for milling ore. The ledge was a little narrow seam of quartz carrying free gold, but Mr. Macfarlane says it did not amount to anything. Mining has been kept back considerably at Ivanpah during the past year by litigation.

SIERRA.

ITEMS.—Mountain Messenger, Sept. 27: The Bonanza company, at Flowland Flat, will be in working order by January. All the outside work will be completed in a month. Work on the inside is progressing. There is about 225 ft of tunnel to run, 800 ft air-shaft to put in, 10 ft of air-shaft to raise. The shaft is up now 175 ft, and the tunnel is in 3,500 ft. Last week the contractors broke through into the old breasts of the "Empire" and it is certain the Bonanza tunnel is but 5 ft above bedrock, with the bedrock raising ahead at the rate of at least two ft in a hundred. The Virginia company are working off in the old Empire, toward the overgrown, and they have fair prospects and it is hoped the same will continue.

SISKIYOU.

SCOTT VALLEY MINES.—Mr. H. C. Cory, of Elma Mills writes us from these mines and says: The Montezuma claim, opened by Denny & Parker, is working 12 men and realizing from five to 96 ounces of gold per day. They have ground to last them 20 years. The gravel deposit is quite extensive. Hundreds of acres of good ground yet untouched for want of capital to work them. It forms the selvage or border of Scott valley, in which all kinds of grain, fruit, vegetables and butter and cheese are produced in abundance. Vein mining in this county will last for ages. In the French Creek lead the quartz vein can be traced for miles by its croppings. It is 5 ft thick, and prospects well, the lowest assay being \$23 gold and \$3 silver. The vein is located so convenient to the valley that many farmers have located claims and doing enough work on them to pay for the capital comes. There is a lot of country 60 miles wide running through the county in which veins of untold wealth are known to exist, the leading ones being the Black Bear, Klamath, Evening Star, Morning Star, Johnson, Lindsey, Turk, Abbot, Cornish, Empire, and many others, and lastly the Beaver Creek diamond mines, near the Oregon line.

SONOMA.

GREAT EASTERN QUICKSILVER MINE.—Fredericksburg *Enterprise:* An important improvement now being made at the mine is the addition of hoisting works, capable of working 600 or 700 ft levels; there will be an ore cage and a double stroke pump, the latter being needed to free the lower levels of water. A kiln of 60,000 bricks has recently been burned at the mine, and the little Eames furnace is to be taken down; another one will be built upon its foundations, with Haskins & Hall's patent ore chamber attached. There is now in use at the mine a 26-ton Jack well furnace, almost new, and in fine condition. The improvements in the way of buildings, roads, etc., are numerous and substantial. At present the hoisting works are being adjusted, and by next week it is expected that the mine will be in full operation. D. H. Haskins is the Superintendent.

TRINITY.

RICH GRAVEL.—Journal, Sept. 27: In putting in four 12-ft boxes in the Oregon Gulch Mountain claim last week, Superintendent Loderick removed the gravel to the depth of four ft and ten ft in this. This was washed and yielded a little over \$500. And this from gravel taken from the bedrock. There is more gold in this State than there is in any other place in this State. A good supply of water is all that is needed to make it the best paying hydraulic mining property on the coast.

TUOLUMNE.

BONAZA.—The Union Democrat of Sept. 27th says: On Saturday last there was shipped through Wells, Fargo & Co.'s Express to San Francisco, the snug little sum of \$189,000, which was extracted from a pocket in a quartz vein in the bowels of Gold hill, which lies adjacent to Pictet hill, west of the Episcopal church. The fortunate owners are Divoll, Bray and Clark, three energetic, experienced and persistent pocket-hunters. In early days it is reported that a pocket of \$60,000 was taken out of the same hill, and much prospecting has been done since, but nothing found until the present strike. The present owners of the bonanza have been working in their claim but a little over a year, and none of the quartz was crushed in a mill, but in a hand mortar. It is estimated that in all they have taken out over a quarter of a million dollars. There are plenty more pockets around Sonoma, and all it needs to discover them is some experience in this kind of mining and good staying qualities. Quartz mining interests are doing well, and placer mining is reviving in the old gulches where it was abandoned in the more palmy days of 1849 and the following years. *Item.—Independent, Sept. 27:* The Starr King vein is looking finely. In the shaft, 155 ft deep, they have struck another 34-inch lode which shows free gold. Still sinking, in easy ground. There is only water enough to run the mill a few hours a day, until the rains come. The Starr King is located four miles east of Summerville.

YUBA.

MEADOW LARK MINES.—Appel: These old mines, which made many Marysvillians rich in their imagination several years ago, are not yet abandoned. It is said the ore reduced recently was some that had been exposed to the weather for a long time, and many claim there is less reason for this than from the mine. The ore to be tested is now being extracted from the U. S. Grant mine. The result of the test will be known in a short time. From the last lot of ore 80% of the gold contained was extracted and saved.

NEVADA.

OPHIR.—Gold Hill News, Oct. 1: A very interesting formation has been encountered in the joint Mexican winze from the 2100 level, the bottom having taken a plunge into low-grade quartz, in which it still continues. The dip of this formation where encountered is to the west, and similar to that encountered in the incline where first struck, but which afterward took a regular eastern dip. The joint Mexican crosscut west on the 2000 level is again in a harder formation, the face 102 ft from the main lateral drift.

SIERRA NEVADA.—The east drift, 2200 level is making an average of three ft per day through soft vein porphyry. Total length, 85 ft.

UNION SHAFT.—The bottom of the shaft dropped into ore last Saturday of good quality, and this morning was still in ore giving good assays. This ore was struck 40 or 50 ft above where it was expected. The diamond drill has already proved its existence on the level below.

CON. VIRGINIA.—The water flow from the face of the joint Mexican crosscut west on the 350 level has been piped down to the Sutter tunnel level. The flow has decreased to about eight inches. The south lateral branch is making three ft per day and is encountering more quartz; total length, 120 ft. The raise from the 1550 level is still in porphyry and quartz through which it is making steady progress.

CALIFORNIA.—The streak of ore encountered upon the 2150 level is being raised up near where the drift on that level connecting with the Ophir crosses it. It is also being followed north and both workings are in good milling ore of the usual width.

EXCHICHER.—A crosscut has been started west 100 ft from the Alpha winze, on the 2400 level, and different crosscuts will be run at various points in the mine, to prospect the ground thoroughly from the footwall to the hanging wall of the vein.

GOLD MOUNTAIN.—Preparations have been completed for continuing the south winze on down to the 2500 level. The joint Alpha crosscut west, 2000 level, is making good progress and cutting quartz in stringers.

MEXICAN.—The joint Union crosscut on the 2000 level is in 147 ft in soft ground, requiring to be closely timbered, and through which only 2 1/2 ft per day has been driven. The joint Union winze from this level is down 106 ft, and continues full wet, vein material. Average sinking per day, about 2 ft.

NEW YORK.—The incline is being pushed rapidly on down, and is encountering stringers of quartz giving low assays.

LEVATHIAN.—The face of the north lateral drift on the 750 level of yesterday nearly all in low grade ore assaying from \$5 to \$10 per ton. This is considered, however, to be merely a bulge or output from the main ore vein, in the west wall of which this drift is being run. The south lateral drift on the same level, also following the west wall, is simply in a very hard, black dyke formation at present, with occasional streaks of quartz.

GOLDEN STANDARD.—The vein formation now being encountered in the Golden Standard tunnel is becoming more moist and treacherous as advancement is made.

SILVER HILL.—The face of the crosscut east on the 1300 level is in a mixture of clay, porphyry and quartz, the latter carrying low grade ore; total length of crosscut, 450 ft.

SAN JACINTO DISTRICT.

ITEM.—Silver State: Parties owning several mining claims in this district on the west side of the Humboldt river, opposite Rye Patch, have put up a 4-stamp mill to run by water power. Valuable ledges have been uncovered.

UNIONVILLE DISTRICT.

OLD MINE.—Silver State: Major Lathlean, of Unionville, informs us that he is now at work on the old Leroy mine, one of the first claims located in that camp. He is drifting on the lead, and has a four-ft vein of ore which assays from \$50 to \$150 per ton in silver. This ledge, which crops out boldly on the side of a high mountain, was abandoned by its original owners, who expended considerable money in running a tunnel to intersect it. The tunnel was designed to cut it at a great depth from the surface, but long before it reached the ledge the funds of its projectors were expended, and they abandoned the claim, which they never prospected, in disgust, although there was a fine looking ledge bearing considerable ore in sight.

PIOCHE DISTRICT.

DAY MINE.—Record: The ore is opening out well and

[CONTINUED ON PAGE 220.]

Origin of Mineral Veins.

By J. ARTHUR PHILLIPS, F. C. S., Etc.

The origin of mineral veins is a subject which has long occupied the attention of writers on natural history; and numerous theories have at different times been framed with the object of explaining the nature of the causes by which they are supposed to have been produced.

An enumeration and classification of those which had been brought forward previously to 1838 is given by Baron von Herder in his work on the Meissen adit, published in that year.

This may be briefly summarized as follows:

1st. *Theory of contemporaneous formation.*—According to this, lodes are not mineral matter occupying previously existing fissures, but were formed either contemporaneously with the enclosing rock, or were subsequently produced by metamorphic action.

2d. *Theory of lateral secretion.*—Lodes are fissures filled by various mineral substances derived from the rocks enclosing them.

3d. *Theory of descension.*—By which veins are explained as being produced by the filling of fissures by materials introduced from above.

4th. *Theory of ascension.*—This teaches that veins are the result of deposits of mineral substances which have been introduced into fissures from below.

Four distinct modifications of the last theory may be divided into as many sub-classes.

a. *Infiltration.*—The material was introduced by aqueous solution.

b. *Aqueous vapors.*—The fissures were filled with mineral matter introduced by the agency of steam.

c. *Sublimation.*—The substances constituting mineral veins were introduced in a gaseous condition by sublimation.

d. *Injection.*—The materials forming veins, have, according to this view of the question, been introduced in a state of igneous fusion.

The formation of veins has been the subject of much speculation since the date above referred to; and various authors have either advanced new theories, or have advocated more or less important modifications of those before promulgated.

Among the most worthy of consideration may be cited the researches of Mr. R. W. Fox, who, after ascertaining the existence of electric currents in many of the metalliferous veins of Cornwall, suggested the probability of this force having acted on the various metallic sulphides and chlorides, dissolved in the hot water traversing fissures, in such a way as to determine the peculiar mode of their distribution. He has also endeavored to account for the prevalence of an east and west direction in the principal Cornish lodes by their position at right angles to the earth's magnetism.

Weighty objections to this theory, however, have been pointed out by W. J. Henwood, as well as by other experienced miners; and observed facts would indicate that the general direction of veins, in different mining districts, varies so entirely, that it probably depends rather on lines of fracture than on the action of voltaic currents. In fact, Von Beust, in his criticism on Werner's theory (1840), appears to have conclusively demonstrated that the majority of lode fissures have been produced by volcanic or plutonic agency.

It is well known that mineral veins are usually found in regions in which igneous rocks are abundant, and in situations where they have burst through crystalline or other stratified deposits. Lodes also more frequently occur in rock formations of great age than in recent ones; and certain classes of them (as, for instance, those of oxide of tin) are only found in the oldest rocks.

Sir Charles Lyell, when speaking of chemical deposits in mineral veins, remarks: "We know that the rents in which ores abound extend downwards to vast depths, where the temperature of the interior of the earth is more elevated. We also know that mineral veins are most metalliferous near the contact of plutonic and stratified formations, especially where the former send veins into the latter—a circumstance which indicates an original proximity of veins, at their inferior extremity, to igneous and heated rocks. It is moreover acknowledged that even those mineral and thermal springs, which, in the present state of the globe, are far from volcanoes, are nevertheless observed to burst out along great lines of upheaval and dislocation of rocks."

It is generally admitted by geologists that igneous canoes have been in active operation in all past ages of the world. They have been constantly changing their areas of activity on the earth's surface; and those districts which are now great centers of volcanic action were, at remote geological epochs, in a state of perfect tranquillity; on the other hand, districts in which violent eruptions took place at former periods have often been entirely free from volcanic eruptions during later geological times. It would appear that the last expiring efforts of volcanic action frequently manifest themselves in the form of geysers or boiling springs, which, in addition to pouring forth steam and water holding various salts and minerals in solution, give off carbonic acid, sulphureted hydrogen, and other gases.

Hot and boiling springs are exceedingly numerous in some of the mining regions of the Pacific States of North America, and present phenomena possessing the highest degree of interest to the geologist.

The Steamboat Springs, seven miles north-

west of Virginia City in the State of Nevada, are probably the most remarkable of those yet discovered. They are situated at a height of 5,000 feet above the level of the sea, near the foot of the eastern declivity of the Sierra. In this locality the granite is traversed by numerous parallel fissures, which either give out highly heated water or simply eject steam. The principal group of crevices, of which the direction is nearly north and south, comprises five longitudinal openings, extending nearly in a straight line for a distance of more than 1,160 yards. These are often full of boiling water, which sometimes overflows and escapes in the form of a considerable rivulet, whilst at others it does not reach the surface, although violent ebullition is heard to be taking place below. These waters are slightly alkaline, and contain sodium carbonate, sodium sulphate, and common salt. There is along the whole line an escape of carbonic acid, sulphureted hydrogen being also evolved from certain points in notable quantities.

Silica, sulphur and oxide of iron are deposited; and the fissures are lined on either side (sometimes to the thickness of several feet) by incrustations of more or less hydrated silica. This is constantly accumulating on the sides, whilst a longitudinal central crevice affords a passage for the escape of steam and boiling water. This silica forms a series of semi-crystalline bands parallel with the walls of the fissure, and often presents the comby appearance peculiar to the beds of deposition so frequently observed in mineral veins.

At some distance to the west of the line of fissures now in a state of activity, is another group of longitudinal siliceous deposits, also presenting a central crevice, from which steam and carbonic acid still escape, although no longer traversed by hot water. The silica from this locality contains oxides of iron and manganese, together with traces of copper, and minute crystals of iron pyrites. It has also been stated to be sometimes slightly auriferous; but I was unable to detect this metal in any of the specimens selected for examination.

The granite in which the fissures occur is covered, both on the eastern and western sides of the valley, by a compact basalt.

On analysis the deposited silica was found to contain from 4.72 to 6% of water; and on being boiled, in a finely divided state, with a strong solution of caustic potassa, 6.68% of its weight was dissolved.

Thin sections of this substance examined under the microscope show the reniform structure of chalcedony, with patches of amorphous silica, stains of oxide of iron, and geodes of crystalline quartz. Some few specimens also contain minute crystals of pyrites. The crystals of quartz lining cavities filled with amorphous silica become very distinct when examined by polarized light; but the chalcedonous markings then almost entirely disappear.

At the "Sulphur Bank" on the shores of Clear lake, California, is a solfatara some six or seven acres in extent, where a much decomposed volcanic rock is traversed by innumerable fissures, from which steam, together with carbonic and boracic acids, is continually issuing. Sulphur is deposited on the sides of the crevices; and gelatinous silica is found coating chalcedony and opalescent silica in various stages of formation, from the gelatinous state to that of the hardest opal. This indurated silica is sometimes nearly colorless, but is more frequently permeated by cinnabar and iron pyrites, or blackened by a tarry hydrocarbon. Cinnabar is also found in striae, and occasionally in veins, as well as in concretionary masses of considerable size.

Sections of chalcedony and semi-opal from this place, when examined under the microscope, are often found to enclose crystals of pyrites, together with crystalline cinnabar, although the latter mineral has generally been deposited in an amorphous state. A specimen of chalcedony taken from one of the fissures in the sulphur bank, which on being first broken was exteriorly so soft as readily to receive an impression of the nail, had on reaching this country become hardened, and had assumed the ordinary characteristic of that mineral. Thin sections of this specimen show a structure resembling fine-grained fortification agate, and are traversed by numerous fissures filled by opaque oxide of iron.

The vein matter of lodes on the Pacific coast of North America has generally so many characteristics in common with deposits produced by solfatara action, that various geologists, who have examined that region, have arrived at the conclusion that the two are the result of similar causes.

Von Richthofen remarks that "the process which immediately follows the opening of fissures at or near active volcanoes, is the violent emission of steam. A crevice in this state is called a *solfatara*. It has been proved by Bunsen for the volcanoes of Iceland, by Bousseingault for those of the South American Andes, by St. Claire-Deville for those of the Canary Islands, and by myself for the tertiary volcanoes of Hungary and Transylvania, that every solfatara, in the course of time, passes through two stages, in the first of which the steam is accompanied by gaseous combinations of fluorine and chlorine, in the second by those of sulphur, while a third one is ordinarily marked by the emission of carbonic acid and combinations of hydrogen and carbon; at which time the term *solfatara* is no longer applicable. We have in the elements evolved during the first two periods, all the conditions required for filling the Cometock fissure with such substances as those of which the vein is composed."

W. P. Blake describes the lodes at Bodie Bluff, nine miles west of the town of Aurora, as being of a character favorable for the production of gold, and then goes on to say: "They are all alike in this respect, and doubtless had the same origin. The quartz, instead of being a solid homogeneous mass, is formed in thin layers or coats, one over the other, like sheets of paper or pasteboard, with irregular thin seams or openings between. This structure, with other peculiarities, indicates that the veins were deposited gradually in the fissures by thermal springs, similar perhaps to those now existing at various points along the eastern base of the Sierra Nevada, as, for example, at Steamboat Springs, Washoe."

Daubree observes that veins can have been but very rarely filled either by fusion or sublimation, but that, on the contrary, the material of which they are composed have been deposited from solution in highly heated waters.

The late M. de Senarmont has shown that the principal minerals found in veins may be produced in a crystalline form by the aid of water heated to temperatures varying from 130° to 300° Centigrade. Among the minerals which were thus obtained may be enumerated quartz, apatite, iron, the carbonates of manganese and zinc, sulphate of baryta, sulphide of antimony, mispickel, red silver ore, etc.

In the present state of our knowledge we are unable to explain all the various phenomena which have been observed in connection with the origin, composition, structure and mineral constitution of veins; but a careful consideration of ascertained facts would appear to lead to certain general conclusions, forming a sort of skeleton map, of which the details remain to be filled in by the aid of further research.

First. Metalliferous lodes are more numerous and productive in the vicinity of igneous rocks than elsewhere.

Secondly. There is abundant evidence of volcanic eruptions having taken place during all periods of geological time.

Thirdly. Solfatara action and thermal springs are often the latest active evidences of volcanic disturbance.

Lastly. Crystalline quartz, iron pyrites, sulphide of mercury, and various other minerals are at the present time being deposited by solfatara action, in veins possessing many of the characteristics of ordinary lodes.

Is it then unreasonable to suppose that many mineral veins may have originally been fissures produced by volcanic disturbances, which have subsequently become filled during the ensuing periods of solfatarae and hot springs? This view of the subject would appear to indicate the nature of the connection existing between such veins and eruptive rocks, and also to explain why they should generally be of more frequent occurrence in the older rocks than in formations of comparatively recent date.

Carefully conducted analyses, executed on large quantities of the waters issuing from active solfatarae and thermal springs, might probably afford valuable information on this subject; but it must not be forgotten, as observed by M. E. de Beaumont, that we cannot expect the contents of hot springs and mineral veins to be identical. The more insoluble of the bodies in solution, both simple and compound, will be deposited in proportion as the temperature and pressure decrease; the more soluble only being discharged in the waters issuing from the surface.

The occurrence in lodes of minerals exhibiting pseudomorphic forms, apparently produced by their deposition in molds left by the removal of crystals of other substances, and the presence in drusy cavities, of stalactites of calcite, quartz, pyrites, etc., indicate that a partial decomposition and re-arrangement of some of their constituents has been effected by the action of water at comparatively low temperatures. There can also be little doubt that fissures and cavities have sometimes been filled by infiltration from the enclosing rocks, as well as by the percolation of meteoric waters from the surface. The operation of these agencies is perhaps, in most instances, extremely slow, although, according to R. B. Smyth, even gold, under certain conditions, may be deposited in appreciable quantities within comparatively short periods. This author states that, in the gold-fields of Victoria, pieces of highly mineralized fossil wood, taken from the deeper workings, as well as timber used for supporting galleries, which had remained in the mine for some years, have exhibited, under the microscope, particles of gold adhering to and intermixed with crystals of iron pyrites, all through the central parts of the wood. This is confirmed by Mr. Ulrich, who says that in the gold drifts pyrites is often found incrusting or replacing roots and driftwood, and that example, assayed by Messrs. Daintree, Latta & Newberry, have yielded amounts of gold varying from a few pennyweights to several ounces per ton. According to Mr. H. A. Thompson, a specimen of pyrites from the center of an old tree trunk gave by assay above 30 ounces of gold per ton.

On examining pyrites forming the substance of fossilized trees found in the deep diggings at French Corral, Cal., I was unable to detect any decided traces of gold; but assays of several specimens of the cementing pyrites of an auriferous deposit of tertiary age, and probably belonging to the later Pliocene period, invariably afforded a small amount of that metal. A microscopic examination of the gold in this pyrites showed that the fragments were frequently angular, and apparently unwaterworn.

In order to ascertain whether waters travers-

ing mineral veins contain an appreciable quantity of any of the constituents of the lodes through which they pass, I subjected three specimens, obtained from deep Cornish mines, to careful analysis. I am indebted for the samples operated on to Mr. Francis Oats, of Botallack, a member of the Miners' Association of Cornwall, who in each case collected about six gallons of the water issuing from the bottom of a level, where the lode beneath remained intact, in clean and carefully stoppered glass bottles.

The amount of soluble matter in the specimens examined is small, and the constituents do not differ materially from those which might be expected to occur in ordinary well-water from the same district. The third sample evidently consists of a mixture of sea-water with water derived from other sources.

The solid contents, however, are considerably less than in sea-water, and consequently, in order to institute an approximate comparison between them, we will suppose sea-water to have been diluted with distilled water until the total amount of fixed constituents has been reduced to that contained in the water from Botallack.

Copper, zinc, lead, tin, etc., were carefully sought for by the usual tests without success; but the spectroscopic was only employed for examining the alkaline chlorides with the flame of an ordinary Bunsen gas-burner. It is, however, probable that traces of various substances, present in such minute quantities as to escape detection by ordinary means, might be found by spectroscopic observation with the assistance of a powerful induction coil; and I therefore propose to make further investigations by the aid of this instrument, and also to operate on very large quantities of the various waters subjected to analysis.

A difficulty in all investigations of this class must necessarily arise from the impossibility of determining the distance which the waters, in each case, have passed through the several lodes. It is consequently quite possible that samples of water may have been examined which, after passing for long distances through the enclosing rocks, may have ultimately entered the veins a few feet only from the point at which they were collected.

Should, however, one specimen of water be found to contain appreciable amounts of the constituents of the vein from which it issued, whilst another is comparatively, or entirely, free from them, it might be inferred, all other conditions being the same, that the first had traversed a greater extent of vein-matter than the second.

It is evident that much time must be expended and numerous analyses made before reliable conclusions can be arrived at; and should waters containing appreciable quantities of the constituents of the veins from which they have issued be discovered, an important question will still remain unanswered.—Is the water ascending through a metalliferous vein ever the medium from which fresh deposits of mineral matter are being produced at the present time? or does it, on the contrary, take up and carry away some of the constituents of the lode, giving rise to new combinations and a re-arrangement of its elements? That both these actions may sometimes be going on simultaneously does not appear improbable.

AN AGED AND HISTORIC SHIP.—The ship that carried William III. (Prince of Orange) to England, when he went to take possession of the Monarchy, had a long life. It was named the Princess Mary, and was built on the Thames. It was more than half a century old when William landed from her at Torbay, November 4th, 1688. She was 80 feet 3 inches long, 23 feet broad, double decked, with two masts, square rigged. Her earlier name is said to have been Brill, but this we believe is not established. She was christened the Princess Mary after the King's consort, when she was selected to bear the fortune of the monarch to his new kingdom. During the whole of his reign and that of his successor, Queen Anne, she was used as a pleasure yacht and was kept in thorough order, some of the repairs being quite extensive. In 1714, when the vessel came into possession of George I., she ceased by his order to form part of the royal establishment. About 1750, in a fit of economy, the government sold her to the Messrs. Walters, of London, who christened her Betsy Cairns after a favorite West India belle of that name. After a score or more years in the West India trade, during which she was known as a staunch vessel and a fast sailer, she was sold to Messrs. Carline, of London, who employed her as a collier to take coals from Newcastle to the great metropolis. About the year 1825, more than two centuries probably from the date she was launched, she was purchased by Mr. George Finch Wilton, of South Shields. On the 17th of February, 1827, she was taking a cargo of coals from Shields to Hamburg and struck upon the Black Middener, a dangerous reef of rocks north of the mouth of the Tyne, where a few days afterward she became a total wreck. Her remains were eagerly purchased, and innumerable snuff-boxes and other souvenirs were made from the old oak that had been so indestructible through more than 200 years.

ALKALINE METALS.—Schiel has observed that the alkaline metals do not retain their brightness if kept in a stoppered bottle under rock-oil, and he ascribes the fact to the formation of ozone.

The Somorostro (Spanish) Ore Mines.

The center of the Somorostro iron district is situated about 7½ miles west-northwest of Bilbao, and at an equal distance from the shipping stages on the river Nervion, between Bilbao and the sea; but the known deposits are scattered over a large area, some being close to Bilbao, and others nearly 19 miles in the north-west. The principal mass is elliptical in shape, about 2½ miles long by 1½ miles wide. Its thickness is unknown, but workings have been carried in it to depths in some places of 246 feet, and in others of 105 feet. It consists chiefly of brown hematite, with here and there blocks of unaltered spathic ore. The ore contains, in its dried state, from 50% to 64% of metallic iron, with about 1% of manganese, and little phosphorus or sulphur. It is of cretaceous age, being in some places interposed between undoubted cretaceous strata, and has probably been deposited by hot springs highly charged with carbonate of iron. In some localities the ore crops out on the surface, and is obtained by simple quarrying. It is all got by blasting, in open workings, and is conveyed, first, by ox carts or by wire tramways to the railway lines, and then by rail to the shipping places.

Two systems of wire-rope conveyance are in use, that of Hodgson and that of Bleichert. Bleichert's arrangement is the more recently introduced, and, though the more expensive system, is preferred, as being cheaper in working, and capable of carrying twice as much ore per day. In it the main cables are fixed, and serve merely as rails for the trams or tubs which are suspended from them to run on, and these are drawn along by a second lighter running cable. The cost of transport, for a distance of two kilometers (say 1½ miles), is by Hodgson's wire-rope line about 7d., and by Bleichert's 4d. per ton.

The mines are connected to the shipping places by five lines of railway, either in work or under construction. The railway wagons are loaded by hand, and are on or bottom tipping. The shipping stages are of timber, and are generally normal to the river; the wagons being run out singly, emptied, and brought back. The ore is filled into the vessels through inclined shoots, or, in one instance, through a vertical "spout," over which the bottom tipping wagon is discharged. The average cost per ton of the ore, delivered on board ship, is approximately as follows:

	Francs.
Quarrying.....	1.30
Conveyance to the railway, by a Bleichert wire-rope line.....	0.46
Filling the railway wagons, carriage to the shipping place, and putting on board.....	2.08
Duty.....	0.13

Total.....3.97 say 3s. 2d.

The har at the mouth of the Nervion is a great obstacle to navigation. It practically closes the entrance during half of each month, and vessels of great draft can pass it only at spring tides.

The most advantageous type of vessel for the trade is a steamer drawing 13½ to 14 feet of water, carrying a cargo of 1,000 tons, and with engines of 100 to 120 H.P. With such vessels, going out in ballast, the cost of freight from Bilbao to Calais or Rotterdam is about 7s. 8½d. per ton.

The quantity of ore shipped in 1877 was 964,533 tons; and in the first 10 months of 1878 it was 1,040,000 tons.—*Revue Universelle des Mines.*

ABOUT BELLS.—In making large bells, loudness rather than pitch is the object, as the sound can be conveyed to a much further extent. This accounts for the enormous weight of some of the largest bells. St. Paul's, London, weighs 13,000 pounds, the bell of Antwerp, 16,000 pounds; Oxford, 17,000 pounds; the bell at Rome, 19,000 pounds; Meeblin, 20,000 pounds; Bruges, 23,000 pounds; York, 24,000 pounds; Cologne, 25,000 pounds; Montreal, 29,000 pounds; Erfurt, 30,000 pounds; "Big Ben," at the House of Parliament, 31,000 pounds; Sens, 34,000 pounds; Vienna, 40,000 pounds; Novgorod, 69,000 pounds; Pekin, 139,000 pounds; Moscow, 141,000 pounds. But, as yet, the greatest bell ever known is another famous Moscow bell, which was never rung. It was cast by the order of the Empress Anne in 1653. It lies broken on the ground, and is estimated to weigh 443,772 pounds. It is 19 feet high and measures around the margin 64 feet.

THE PARADOX ENGINE.—Among the many wonderful things in Power Hall, Cincinnati, is the Paradox engine, represented by Messrs. Tilden & Gray, of that city. In this engine there are no stuffers to pack or governor belts to break. It has no cross-heads to adjust, or eccentrics to slip, and as the moving parts are not exposed, there is no danger of getting caught in the machinery, nor is there any splashing or dripping of oil, which is such a disagreeable thing in many engines. Since no adjustment of the parts is required, any engineer, however unskilled, so he knows how to keep fire under and water in the boiler, can run it. As we have already maintained, perfection in mechanism consists in simplicity.—*American Inventor.*

USEFUL INFORMATION.

Splitting Paper.

It is one of the most remarkable properties of that wonderful product—paper—that it can be split into two or even three parts, however thin the sheet. We have seen a leaf of the *Illustrated News* thus divided into three parts, or three thin leaves. One consisted of the surface on which the engravings are printed; another was the side containing the letter-press, and a perfectly blank piece on each side was the paper that lay between. Many people who have not seen this done might think it impossible; yet it is not only possible, but extremely easy, as we shall show.

Get a piece of plate glass and place it on a sheet of paper; then let the latter be thoroughly soaked. With care and a little dexterity, the sheet can be split by the top surface being removed. But the best plan is to paste a piece of cloth or strong paper to each side of the paper to be split. When dry, violently and without hesitation pull the two pieces asunder, when part of the sheet will be found to have adhered to one and part to the other. Soften the paste in water, and the pieces can be easily removed from the cloth.

The process is generally demonstrated as a matter of curiosity, yet it can be utilized in various ways. If we want to paste in a scrapbook a newspaper article printed on both sides of the paper, and possess only one copy, it is very convenient to know to detach the one side from the other. The paper, when split, as may be imagined, is more transparent than it was before being subjected to the operation, and the printing ink is somewhat duller; otherwise, the two pieces present the appearance of the original if again brought together.

Some time ago the information of how to do this splitting was advertised to be sold for a considerable sum. We now impart it to all our readers gratuitously.—*B. and O. Printer and Stationer.*

CAST-STEEL.—A London metallurgist claims to have produced a high quality of cast-steel at a considerably reduced cost by re-carbonizing fused metal. The Siemens or Bessemer process furnishes the required kind of metal, which, after being forged, rolled, and brought to the desired size and form, is submitted to a re-carbonizing process in closed vessels of any adequate heat-resisting material, and the carbonizing substance may be such as are employed in the usual cementing process. Wrought-iron vessels about five-eighths of an inch thick, and of such a form as will best suit the purpose for which the steel is intended, are preferred. The covers project beyond the sides of the box, in order to admit of their being firmly fixed with keys or wedges, and the interstices are then tightly filled with clay. An ordinary gas or reverberatory furnace may answer for the process.

PERCUSSION-LOCKS.—The percussion-lock, it appears, was invented by an English clergyman—Rev. Mr. Forsyth—in the year 1807. In the year 1500, all fire-arms were fired by a lighted match carried in the hand. About 1510 the match-box was introduced, which was so far an improvement that the lighted match was attached to the gun. But a shower of rain was still an effectual damper of the hottest fight. Soon after the wheel lock was invented, which produced ignition by the rapid revolution of a steel wheel against an inflammable substance. This lock was in use during the wars of the Commonwealth. The well-known flint-lock was introduced about the year 1692, and was in universal use down to the battle of Waterloo. The percussion-lock, for many years after its invention, was only employed in the slaughter of birds and beasts.

GLASS WATER AND GAS PIPES.—An important discovery has been made and patented by Capt. John B. Ford, of Jeffersonville, Ind. This is the manufacture of gas, water and sewer pipe from glass. The glass can be made from one-half to one and a quarter inches in thickness, according to the diameter of the pipe, and it is claimed that it will stand a greater pressure than iron. As the materials for its manufacture abound in all sections of the country, it is proposed to make it near where it is to be used. It is claimed that it can be made at a cost of \$8 per ton, of course much less than is paid for freight on a large portion of the iron pipe now used.

BORAX WATER.—Borax water will instantly remove all soils and stains from the hands, and heal all scratches and chafes. To make it, put some crude borax into a large bottle, and fill with water. When the borax is dissolved, add more to the water, until at last the water can absorb no more and a residuum remains at the bottom of the bottle. To the water in which the hands are to be washed after gardening, pour from this bottle enough to make it very soft. It is very cleansing and very healthy. By its use the hands will be kept in excellent condition—smooth, soft and white.

PETROLEUM-PROOF CEMENT.—A cement peculiarly adapted to stand petroleum or any of its distillates, is made by boiling three parts of resin with one of caustic soda and five of water. This forms a resin soap, which is afterward mixed with half its weight of plaster of Paris, zinc white, white lead, or precipitated chalk.

A QUICK-SILVER-TIGHT FLUME.—Mr. Bryan Tyson, of this city, says: "It is difficult to so construct a flume of great length that a leak will not occasionally occur. These leaks are most frequent where the ends of the bottom boards join together, and may be prevented as follows: Have the joints fit closely on the bottom side, but about one-fourth of an inch open on the top. Procure some white lead and reduce to a proper consistence with linseed oil. Next, a good supply of wedges of the proper thickness. Then coat well with this lead, and drive into the openings formed as aforesaid. Any defects in workmanship can thus be securely and permanently remedied. It is believed that the lead will prevent the wedges from working up, or at least I have never seen any, treated as above, work up. If you are situated near a box factory the wedges had best be sawed."

BELT LACING, ETC.—Among the recent practical inventions is one patented by Mr. A. C. Krueger—a process for tanning rawhides for belting, lacing, etc. Mr. Krueger's process for preparing the hides for unhairing is by steam. After being unhaird, thoroughly fleshed and passed through the fresh water soak, they are removed to a bath containing a chemical solution which readily unites with the component parts of the hides. In due time the hides are taken out of the bath, thoroughly dried, and then placed in the stuffing wheel, where they are made to receive a due proportion of grease, and become very mellow. They are then placed on the stretcher and thoroughly stretched, and from there to the grease curing table for the last finishing touch. Goods made from this material are said to give great satisfaction everywhere.

TO PREVENT THE CRACKING OF GLUE.—Glue frequently cracks because of the dryness of the air in rooms warmed by stoves. An Austrian paper recommends the addition of a little chloride of calcium to glue to prevent this.

GOOD HEALTH.

Poisonous Fishes.

The *Scientific American* in alluding to cases of poisoning by eating certain kinds of fishes, says: "Grave and even fatal accidents of this nature have usually occurred in the less civilized portions of the globe; and the phenomenon itself is very complex. There are a large number of suspected species; and in some of these certain individuals alone seem to be possessed of the toxic property, and even in these the danger resulting from using them as food disappears at certain seasons of the year. Finally, ichthyology is such a difficult study that few physicians are well enough acquainted with the subject to accurately determine the genera or species of the poisonous fishes that they meet with in their travels."

The *Annales d'Hygiene Publique* says that fish poisoning is one of the maladies that afflict Europeans living in Japan. The salmon is the most common toxic fish of Japan. From the spring onward this fish is out of season, and if eaten after that period of the year occasions the same accidents as follow the eating of tainted meat.

The eating of the *katsuo* (bonita) and the maguro occasions severe congestion of the brain and face, in some cases very serious. Some writers believe that it is a morbid element developed in the fish at certain seasons, or that the idiosyncrasies of the patient have something to do with it. This cannot be accepted as the true explanation, for it has been proved that certain fishes, the *Lethrinus nambo*, for instance—can be eaten with impunity until it attains a certain size, say a length of five to five and a half inches, after which it becomes poisonous. The age of the fish, then, would seem to have something to do with its toxic qualities.

Fishes of very diverse genera have been the occasion of grave and even fatal accidents, and they are found in all parts of the globe, but more especially in the torrid zone. Fapenheim gives a list of more than 40 poisonous species. Among these we find mackerels, perches, herrings, sea pikes, and a large number of species belonging to the order *Plectognathes*. The latter order contains five genera that are poisonous. The most common genus of the order in Japan is the *tetradon* or swell fish, the species of which are all known by the general name of *fugu*, and are considered the most dangerous of the poisonous fishes, so much so, in fact, that their sale at certain seasons is forbidden by law. Dr. Goertz, of Yokohama, in a memoir read before the German Asiatic Society of Japan, has given a description of the symptoms observed in these cases of poisoning by the *fugu*. One of these was rapidly fatal, the other two were more alarming, but recovered under prompt treatment. At the beginning of the attack there were violent headache and nausea, quickly followed by great muscular weakness; the pulse, the respiration, and temperature all fell at the same instant, thus denoting the very energetic action of the poison upon the nervous centers with special effect upon the pneumogastric. Dr. Houghton, of Savannah (*Lancet*, 1876, page 939), mentions 13 cases of poisoning by the *Tetradon Hystrix*—one of the Japanese *fugu*—in which the results were identical with those reported by Dr. Goertz. It is somewhat remarkable that

in the three cases given by the latter, and in the 13 of Dr. Houghton, the subjects are stated to have eaten the eggs of the fish.

Congers, pikes, and barbel have long been recognized in Europe as poisonous at certain seasons, and the eggs of the barbel as especially so.

In Japan the liver of the *fugu*, immediately after the spawning season, is considered the most dangerous part of the fish. A few cases of death caused by eating the liver of the fish have also been reported from the Cape of Good Hope, the poison having proved fatal in some instances in less than 17 minutes.

Sea-Sickness.

Many "sure cures" for sea-sickness have been announced from time to time, but they rarely, if ever, prove effectual in all cases in which they are tried. The malady, like headache and dyspepsia, seems to be of many types and degrees, and a remedy that succeeds in one form or phase of it may utterly fail in another. It is well to keep the various methods of treatment in mind, and, if one chooses, he may test them in turn, until he is able to decide which of them is best suited to his personal case.

Dr. Lederich, a French physician, highly recommends the treatment of sea-sickness with colloidion. This had been the means of warding it off from many who were peculiarly predisposed to suffer from it, and had suffered much before. The colloidion is applied with a brush in three successive layers on the epigastric region (over the stomach) and the neighboring parts. It acts in such cases in the same way as in those of peritonitis, where it is a powerful anti-emetic. The *Algerian Journal of Medicine* reports another way of treating sea-sickness. M. Velasco advises injections of 0.005 grain and 0.02 grain of morphia, and says he has experienced its good effects on himself and his family.

A remedy, or rather a preventive of the malady, which we have not seen mentioned in print, but which has been tested and recommended by the physicians on some of the ocean steamers, is bromide of potassium. This should be taken in 20-grain doses, two or three times a day, and, to our personal knowledge, it has worked well in the case of some persons very sensitive to sea-sickness. Tourists will find it convenient to take with them to sea a solution of the bromide prepared of such strength that a teaspoonful contains 20 grains of the salt. This quantity can be taken in a third or half a tumbler of water. We have never known it to fail, but it would not surprise us to learn that it had failed in very desperate cases. One should begin taking it before being exposed, and, should, if possible, get well under its influence before the time of trial comes. In many cases smaller doses would probably answer the purpose; they can be graduated according to the person's susceptibility to the influence of bromide. We have never known it necessary to use it to such an extent as to produce symptoms of bromism.

TYPHOID FEVER FROM DISEASED MEAT.—An epidemic of typhoid fever, interesting in its etiology, followed a musical festival at Zurich, in May, 1878. Out of some 700 assistants, 500 were attacked by the disease, of whom 100 died. The symptoms could not be mistaken, and the autopsies confirmed the diagnosis. A minute inquiry into the circumstances left but little doubt that the epidemic was due to the use of bad veal furnished by an innkeeper of the place. It may be claimed by those who attribute to general causes the power of originating specific diseases, that the typhoid fever was due to a septic poison present in the veal, depending possibly on a beginning fermentation, which was not destroyed by the cooking to which it had been submitted. On the other hand, as the animal from which the meat was taken was sick, it may be asked whether it might not have been suffering from typhoid fever, although this disease has never yet been recognized among animals. It is a remarkable fact that in 1839 a similar but much less fatal epidemic occurred in a neighboring locality. After a reunion that took place under similar circumstances, 440 persons were taken sick with all the symptoms of typhoid fever. It is probable that in this case also the meat of a sick calf gave rise to the disease.—*Journal de Medicine.*

SOUND SENSE.—Sometimes children have a dislike to flesh meat, and when that is the case, it is the last thing that should be forced upon them; indeed, it is not improbable that children would be far better nourished by eggs, fruit, milk and farinaceous food than by flesh meat. "Perhaps," exclaims the Countess of Mountcashell, "we should all be healthier and longer lived if we had never learnt to devour the flesh of animals." Yet in many instances medical men persist in ordering a flesh diet for children who utterly dislike it. It is difficult to see the wisdom of such a procedure on any sound physiological ground whatever.

CHLORAL IN WHOOPING COUGH.—Dr. C. H. Smith reports that in 200 cases of this disease treated with chloral, he has in every case noticed a marked alleviation of the symptoms and shortening of the period of the disease. Only one case lasted seven weeks, and the majority of the cases were well in from two to six weeks. No other remedy was given.—*N. Y. Medical Journal.*

The Week.

The week has been marked by a series of discoveries in precious minerals, which demonstrate what we have always maintained, viz., that there is probably more wealth still in the ground of this State than has been as yet taken from it. Nevada county, particularly, is looming up into increased notoriety. From the reported strikes in the gravel lead of Shultz & Co., near Greenhorn canyon, beyond Banner mountain, and in the Derhec mine, which latter, although denied, seems to be confirmed by reports later than the denial. The "Lone Tree" ledge, on Manzanita hill, an entirely new and unworked ledge, is creating considerable excitement. Many farmers in the Sierras, we are informed, have discovered good paying mines on their ranches, and are profitably combining mining and agriculture. From every quarter come rumors of a mining revival, which seem to indicate the return of the olden-times mining characteristics, without, however, an unhealthy excitement.

The saving of fine gold from tailings, heretofore considered valueless, continues to excite the ingenuity of miners in devising plans and devices for their profitable working. The old New York district at Ivanpah, in San Bernardino county, has become the scene of quite extensive operations, and mills are going up to work up rich ore.

Bodie is still working out good ore and the mines present an improved appearance.

There is no change of importance in the Comstock, with the exception of ore in the Union shaft. The other districts of Nevada are making new developments, particularly in Aurora district, where a very rich discovery is reported near the Real del Monte mill. Some complaints come from Colorado about Eastern parties putting up mining machinery and incurring heavy expense without investigating whether there was ore enough to support them, and finding none to speak of. Of course growing accounts will always be regarded as truth by many, but more injury than good is done by over-estimates, disappointment under-estimating as much as over-estimating has exaggerated.

Hydraulic and Drift Mining in California.

A good deal of attention appears to be directed just now to the business of hydraulic and drift mining in this State. We say in this State, because this auriferous deposits that afford the best sites for this class of operations exist here under the most favorable conditions for easy and profitable exploitation, if they do not also here reach their greatest opulence and expansion. In some other of our west-lying countries these deep placers in a modified form are met with, but no where are they marked by those peculiar features that characterize them in this State, their origin being probably due to different causes. It is in fact doubtful whether those placiers remains known as "dead or hurried rivers," occur elsewhere than in California and, perhaps, in some parts of southwestern Oregon.

Commencing in Tuolumne, they can be traced through the more central mining counties of this State north through Trinity and Siskiyou into Oregon, where they cease or can be no longer identified. Banks of diluvial gravel are found in eastern Oregon, Idaho, Montana and Colorado, affording material often for large and profitable hydraulic washings, but there are under them none of these channels of ancient rivers, the distinguishing feature of the California placiers deposits, and along which alone drift operations can be prosecuted to advantage.

A variety of causes have tended to awaken increased interest in this department of mining. In the first place, the inducements offered for engaging in the business may be considered generally good, this class of mines having paid with more uniformity if they have not always made such large gross productions as many of the ore-bearing deposits. The probable yield and accruing net profit can here be calculated in advance with so much closeness that the investor runs but little hazard in venturing his means where the conditions are at all favorable; and in this element of certainty the business finds its greatest recommendation, more particularly with Eastern investors, who are better suited where there is security with small and sure profit, than where there is only a prospect of big returns accompanied by extra hazard.

Again, this branch of mining is comparatively free from the troubles that so constantly beset vein operations through the necessity for deep exploration, the encountering of low-grade or refractory ores, the pinching out of pay chutes, etc. In its earlier stages, drift mining was attended with sore loss and disappointment by reason of the tunnels, designed for opening up and working these deposits, having been driven on levels that failed to subserve this end; and it was only after an experience running through years of trial that the levels on which these adits should be located came to be ascertained with much exactness. At present few mistakes of this kind occur; the bottoms of the gravel-bearing channels, if not already known, being determined by artesian borings before the exploiting tunnel is located. With this precaution observed there is little chance of error, where formerly nearly all was left to guess work. As a result many have felt encouraged to engage in enterprises of this kind who, with the old-time uncertainties hanging over them, would have carefully abstained from such undertakings. Many improvements have also been made in the ways and means employed for working these deposits, such as the introduction of locomotive engines for hauling in and out the cars, devices for securing better ventilation, increased water supplies, etc. With so much gained, drift mining, without undergoing any sudden or very marked advance, has experienced a silent but healthful growth for the past 12 months or more, with every probability that it will be able to keep up the same for some time to come, as this class of deposits is very extensive in different parts of the State, and but little water is required for working them. The several ridges that compose the Forest Hill divide, Placer county, notably the districts of Todd's Valley, Forest Hill, Bath, Iowa Hill and Damascus, the Liberty Hill divide, in Nevada county, and along the belt extending thence north through the old drift camps of Alleghany, Forest City and Gibsonville, to the head of Slate creek, Sierra county, constitute the principal localities of renewed activity in this branch of placer mining. On the rich bars along Trinity river there is also much more drift mining now being done than for many years past, the gravel here never failing to pay good wages.

While there is even more money being invested just now in hydraulic than in drift mining, the number of new enterprises of the latter kind being inaugurated is not correspondingly large, the difficulty of obtaining the quantity of water indispensable to their success tending to limit their number. Still, a good many hydraulic schemes have been set on foot of late, and never before has there been such a searching after new sources of water supply, and such efforts made to secure these franchises, as during the past summer. Every available stream and eligible reservoir site before neglected has been taken up, while water rights already located have everywhere assumed greater importance, commanding prices that a few years ago would have been considered extravagant and even preposterous. In all this we see only a proper appreciation of the value of these

properties, and an earnest of the large proportions to which hydraulic mining is likely soon to attain, as well as the prosperous future that awaits this industry.

Mining Decisions.

The Secretary of the Interior has decided the appeal case of Chapman *et al.*, vs. Lanig upon the questions of fact. (1) That the land is not shown to be more valuable for mining than for agriculture. (2) That Lanig's pre-emption entry was not made in good faith. The facts of the case, which was gathered from Copp's *Land Owner*, are substantially as follows: Adam Lanig filed a pre-emption declaratory statement for certain land in the Sacramento Land District, alleging settlement Sept. 1st, 1872. He made proof that the land was non-mineral in character on April 12th, 1875, and entered it on April 19th following. A patent was executed on Sept. 6th, 1876, but was not delivered. On March 28th, 1877, J. W. Chapman submitted his affidavit, alleging that the San Andreas mining company, of which he was a member, owned adjoining lands, and had placed machinery and improvements on said tract, valued at \$5,000, by mistake, and that the correct location of said improvements was not known until a recent survey of the land was made. Chapman also claimed that the land entered by Lanig was mineral land, and known to be such by Lanig prior to his entry, and that Lanig had made an agreement for conveyance of the land prior to entry. From the evidence in the case, it was decided that the San Andreas company failed to prove that the land was mineral land, it appearing that it was more valuable for agricultural purposes. Lanig had made satisfactory proof of the non-mineral character of the tract prior to the investigation by the land office, and the burden of proof is upon the parties alleging the land to be mineral. Where lands have been withdrawn as mineral, the burden of proof is upon the person alleging them to be non-mineral, and applying to enter them under the laws relating to the disposal of agricultural lands; but when satisfactory non-mineral proof has been once made the rule is otherwise.

It appeared, however, that Lanig and one Leonard had purchased the possessory title to the land from Michael Shannon and wife, and about one month after filing his pre-emption declaratory statement an agreement was entered into by William Irvine, Adam Lanig and George Leonard in which it was stated that the land was to be entered under the mining laws. It appearing, therefore, from the evidence that Leonard was a joint owner of the land, and that Lanig's entry was made in part for Leonard's benefit, in direct violation of law. Besides this, the agreement shows that Lanig considered the land mining land, and was estopped to deny it. It was held, therefore, that the entry was based upon false proofs, and therefore fraudulent, and the patent ordered canceled.

In the case of John C. Phillips, Eureka, Nevada, the affidavits for continuous posting of notice on claim, and affidavit of compliance with mining laws, etc., in application for patent, were made by an attorney in fact for claimant. These affidavits must be made by the claimant; they cannot be made by an agent.

CORNISH MINES.—In a two-line item in our issue of the 9th ult., taken from an exchange, it was alleged that the "Cornish mines have been worked for over 1,000 years, and are entirely exhausted." We cannot say that we are sorry the item appeared, since it has had the effect of calling out information from C. Le Neve Foster, of Truro, Her Majesty's inspector of mines, which would not have been the case had the item not appeared. Mr. Foster, in a personal letter to us, says: "So far from the Cornish mines being exhausted, we are raising more tin than ever. The deepest mine, Dolerath, 2,280 feet deep, produced last year 1,524 tons of dressed tin ore, which shows that we need not be afraid of depth. I can safely say that Cornwall could easily produce half as much tin again, yearly, if the price were to rise a little. I do not believe that the child is horn that will see Cornwall exhausted."

A CHEAP MILL.—A complete 8-stamp mill was bought in Jim Crow canyon, Sierra county, for \$150 a few weeks since. The mill, with its engine, boilers, etc., originally cost some \$16,000, and only ran two weeks. It has been idle now for some four years, and was bought for the ridiculous sum mentioned to be put in another mine. It is only one of the instances of having a mill and no mine. The engine and boiler were not purchased, as it was impossible to get them out of the canyon where they were without more expense than new ones could be bought for. A mine without a mill is better than a mill without a mine.

To-day there are 7,000,000 barrels, of 40 gallons each, of crude petroleum above ground in the oil regions. This vast amount of heat and light is going a-hecking at 60 cents a barrel, and every hour adds to this ocean of oil, and in spite of the enormous consumption the stock accumulates.

Spontaneous Fracture of Castings.

A large number of disputes arise from the discovery, after use, of fractures in castings. In many cases these fractures are sufficient to destroy the further utility of the castings, or are of such an extent as to render them untrustworthy. In either case, whether the fractures are large or small, they give rise to an accusation against the manufacturers of unsound work, and the reply on their part is unfair strain upon the work, as the castings were sound enough when they left the foundry. It is perfectly possible for castings to be quite sound when they leave the foundry and yet for them to break, apparently spontaneously, after they have been in use, or work, for some time, and this, too, without any great or undue strain upon them. Such fractures may certainly be attributed to neglect on the part of the founders to consider that a casting, when cooling, re-arranges its internal particles or crystals so as to contract upon itself. If this re-arrangement is allowed to go on quietly, and without opposing strain or hindrance, a good sound casting is obtained. If, however, cooling is unduly hurried, or a resistance is set up to the necessary contraction, in the first case an abnormal arrangement of the crystals is obtained, termed "chilled," and in the second place a considerable tension, more or less, is set up in the material to resist its ultimate contraction upon itself. The result, as to whether this resistance to contraction shall at once decide the fracture of the casting in the mold, or whether the fractures will not appear until after use, is simply a question of amount of strain set up in the material, and its power of elasticity and tensile resistance to such strains. As, for instance, supposing that the fluid cast iron requires to shrink $\frac{1}{8}$ of an inch in a foot in becoming cold, and a rigid resistance is offered to the whole of this contraction, the limit of tensile resistance of the material is exceeded, and the casting must part in the mold. As, however, we know that the average resistance to tensile fracture of cast iron is about 7 tons per square inch, and, further, that the modulus of elasticity of cast iron is \$,214 tons per square inch, the ultimate breaking tension of 7 tons would correspond to an elongation of about 1.50 of an inch in each foot. Any resistance to contraction, then, within this amount—viz., a resistance to 1.50 of an inch, out of the whole $\frac{1}{8}$ of an inch per foot contraction—would set up a considerable tensile strain in the material, but of just smaller amount than 7 tons per square inch, which is the breaking strain. Under such circumstances, then, the casting would not necessarily break in the foundry; but a severe shock in handling or tooling the casting may effect the rupture of the part thus abnormally strained very nearly to its breaking point. In ordinary use, also, if forming part of a pumping plant, the continual jar and shock of the pump valves are eminently calculated to decide the fracture of material under undue tension.

Change of temperature is also a powerful circumstance in deciding the ultimate fracture of a casting, which may have been unduly strained by retarding contraction in the foundry, as, for instance, a steam cylinder which is subjected to a considerable range of temperature, or hot and cold water pipes and castings. Even the different temperatures of ordinary weather are sufficient, in many cases, to decide rupture. In all cases of such spontaneous fracture the cause may usually be easily perceived, both from the character of the crack and the form of the casting.

In many cases a crack will develop in the main body of the material, and has its widest part at the center, where often the material is strongest, tapering away imperceptibly at the ends, which do not nearly reach the edge of the casting. Such a crack can clearly only result from internal tension amongst the atoms. This species of fracture may occur in a flat plate, more particularly if it has a large boss in the center. The irregular contraction occurs in this way: The outside rim naturally cools first, and stretches on the hot interior, or compresses the latter in its cooling grip. When, now, the boss and center at last cool, the outside rim has a fixed dimension and is already rigidly set. The center and boss, in cooling, must now occupy less space than they did when hot, and must thus tend to draw away from the rigid exterior. If this resistance to contraction be not too great, and the material have a good elasticity, it is possible that fracture does not occur at the actual cooling, but the whole interior of the plate becomes under a condition of very great and abnormal tension. Under exposure to cold and heat, or even to the ordinary vicissitudes of the weather, this plate will, sooner or later, crack in the way described; that is, a crack will commence to develop at the center and travel towards the edge, but probably stopping before reaching the outside of the plate, so as not to split it actually in two.

The form of casting that develops such fractures must of necessity be in the shape of a rigid exterior circumference or surface, which has first cooled, and of an interior surface or tie, which, cooling after the setting of the exterior, tends in contracting to draw away from that exterior, and thus sets up a very considerable tension in the interior material. The primary fault lies with the designer, in sending to the foundry a casting in form predisposed to such accident.

Manning's Process for Working Ores.

The essential features of this new process are to crush the ore in the battery with hot water and salt, and as much bluestone as the amalgamator will not find to be injurious to the screens; then to run the pulp from the battery through an inclined revolving screen, which will take out all the water desired, and prepare the pulp to run to the pans at the proper thickness for amalgamation. The pans are 5½ feet in diameter and 3 feet deep, one above the other, in steps, from the battery, arranged so that one pan discharges into the other continuously. The ore is not handled from the time it enters the rock-breaker, but kept in a continual move from the rock-breaker to self-feeder; thence to the battery; from there through the revolving screen into the first pan; from it into the next, and so on through each pan and into the settler. From the settler it runs into a large box that will hold, say, five tons of pulp, together with the water. The mill is provided with two of these boxes, and when five tons, or about that much, is collected in the box the spent from the settler is turned into the other box, and the one run full allowed to stand four or five hours, or until the water becomes clear. It is then conveyed by pipe or hose to a tank, from which it is pumped into the hot water tank that supplies the battery. This manipulation of the water makes a saving of nearly one-half the salt and a portion of the bluestone. This return water will sometimes get base, and it is sometimes necessary to precipitate the bases by using the corresponding precipitants once in three or four days; a batch of this water is let run off altogether, and replaced with fresh water.

The shape of the pans for this process is shown in the engraving. The blades, or wings, in the pans are about 26 inches long by 7 inches wide and 1½ inches thick. The blades are set to meet the current of the pulp in an oblique manner, so as to prevent the pulp, when discharged into a pan, from sinking too fast to the bottom. The quicksilver in this process is introduced into the second pan from the battery, and is allowed to drop in continuously from a large quicksilver reservoir placed above the pan. The quicksilver never gets to the bottom

which are set in an irregular shape. Then the water is permitted to run around them and the outside of the maslin until it finds its way to the low end of the drum, where it is allowed to pass out and be returned to the heating tank to again pass through the battery.

The screen thus revolving discharges into the pan. The construction of the pans is somewhat peculiar, so as to make more than the usual friction.

The important feature for silver ores, as will be seen, is the crushing in the battery with salt and hot water. The inventor claims that when the silver ore is fractured by the stamps, in the presence of a hot solution of salt and bluestone, it takes up chlorine from the salt instantly; that it does it quicker and more effectually than at any other time; that the salt can be introduced into the ore for amalgamation; and that he saves from 10% to 15% more than any other way he can work ore by wet crushing and raw amalgamation. He claims also to be able to work the ore at an average cost of \$3.40 per ton, with a 20-stamp mill, and that the labor of at least three men in the mill is saved. The recovery of salt and bluestone from the tailings is another very important feature of the mill. As the solution is screened out of the pulp by means of the revolving screen, and returned to the battery, the pulp goes into the pans in the proper condition for amalgamation.

Mr. T. H. Manning is of Butte, Montana, but is at present at No. 814 Twenty-second street, Oakland, Alameda county. He has applied for a patent through the MINING AND SCIENTIFIC PRESS Patent Agency. Circulars explaining the process and apparatus in detail can be had on ap-

Recent Decisions Relating to Patents, Trademarks, Etc.

By the Commissioner of Patents.

Looms—Greenough vs. Drummond. Decided August 26th, 1879.

1. Subjects of interferences are not words, but things; and the same words must mean the same things in their application to two different devices in interference.

2. A claim for a shuttle-driver embracing a device accurately described as a roller, the function of which is to press (the warping threads being interposed) against a corresponding roller in the shuttle itself with a backward motion, which, while equal to the progressive motion of the extremity of the shuttle-driver

Ice Planes—Ex parte Thompson. Decided August 11th, 1879.

1. Neither the law nor the rules make use of the term "statement of invention," and, of course, do not require that such a "statement" should occur at a certain place in the specification.

2. They contemplate, however, that an applicant shall, at the outset of his specification, point out the particular art, machine, article or composition of matter to which his invention relates, so that the remainder of his specification may be read with reference to some object clearly had in view.

3. The exact scope of the invention as the applicant intends to claim it, need be stated only in the claim itself.

4. A proper designation of the invention, a clear description of its parts, operation, and re-

ARRANGEMENT OF APPARATUS FOR WORKING ORES BY MANNING'S PROCESS.

of the pan and stays there in this process, from the fact that it is continuously fed into the first pan, and is continually running from the first pan into the second, from the second to the third, from the third to the fourth, and from the fourth into the settler, from the settler into the bowl at the bottom, thence into the strainer-bag; from thence the amalgamator, at his leisure, returns the quicksilver to the reservoir above the second pan, and removes the amalgam as often as is necessary. Three pans would be plenty to accomplish good results and do good work, but pans are liable to get out of order at times, consequently the inventor prefers having four pans for every ten stamps; if then one pan should get crippled a small spout is provided to run the pulp over or around the crippled pan, while it is stopped and repaired.

The box at the tail-race is provided with a shaft under the middle, and a ratchet and lever at the end. As soon as the clear solution is drawn off, the operator, by means of the ratchet, elevates one end of the box, introduces a two-inch hose with water, and runs the contents of the box into the tail-race.

The contrivance conveying the pulp from the battery to the revolving cylinder is of sheet iron, and made with descent enough to empty the pulp on the middle of the revolving drum. This drum is constructed of a net wire cylinder, 14 inches in diameter and 10 feet long; over this drawn a sack of unbleached muslin, of medium strength or thickness, as the ore under treatment may require. For ore of a soft nature carrying talc and earthy matter, the muslin should be very thin; for ore carrying heavy mineral and silica, a heavier material should be used. The net-wire cylinder, together with the muslin sack drawn over it tight, is then inserted in a revolving drum. The drum is made of sheet iron, a little larger than the wire cylinder, and on the inside is made fast one-half inch square iron or wooden bars,

plication, by letter or in person, at above address.

A UNIQUE MINE MODEL.—We were shown, a few days ago, by J. S. Byington, a miniature model of the Diamond Peak mine of Nevada county, done in plaster and wood by Mr. Elkins. The outside of the model is a perfect representation of the topography of the county in the vicinity of the mine, with the buildings, works, etc. It is built in sections, and upon being taken apart discloses all the underground features of the mine—shafts, levels, tunnels, veins, stopes, etc.—in perfect imitation. The model has been sent East, and is a suggestion in the right direction towards affording a practical illustration of what cannot so well be derived from the examination of maps. With it, the features of the country and the workings of the mine may be studied with nearly as much profit as a personal investigation of the mine itself.

GOLD IN FRENCH GUIANA.—Large numbers of miners from Cornwall, California and British Columbia, says the *Colonies and India*, are in Guiana attracted by the late discoveries of gold. Rich diggings have also been found in Surinam and Cayenne, which promise to eclipse the riches of California and Australia. One miner with four weeks' labor realized 40 pounds of pure gold. Similar proofs of the abundance of precious metals are numerous. The crowd of prospectors coming to these deposits cause fear that complications will arise through the conflicting interests of English, Hollanders and French, as well as the inhabitants of Venezuela and the Indian tribes. The auriferous deposits lie principally upon the confines of the territory of four different nations, the boundaries to which have never been determined, so that the future of the digging is very obscure.

does not result from frictional contact with the belt occasioned by the progressive movement of the shuttle-driver, the effect being to drive the shuttle in a circular race without displacement of the warp threads, does not interfere with a shuttle-driver containing a device described with like accuracy as a roller, the function of which is to raise an advancing ridge on a strap made fast at either end, which advancing ridge drives the shuttle in a straight race, the effect of the rotation imparted to the roller by its frictional contact with the strap being to diminish the friction between the shuttle-driver and the strap.

By the Acting Commissioner of Patents.

Sheet-Metal Cans—Green *et al.*, vs. Field. Decided July 25th, 1879.

1. The knowledge and use of a completed invention, which shows that it was actually completed and capable of working, if made before the invention of the patentee, is sufficient to defeat the claim of the patentee to priority, although the article invented had been lost or destroyed.

2. To constitute forfeiture to the right of a patent, the evidence must be conclusive in showing that the conduct of the dilatory applicant amounts to such acquiescence by him in the use of the invention by others, or in the claim by another as its inventor, that he is thereafter estopped in asserting title in himself.

3. It is difficult to distinguish forfeiture from abandonment or dedication of a complete invention to the public by the original inventor; but a delay to file an application for a patent, after a patent had been granted to another for the same invention, which was solely the result of advice received from joint applicants' attorney, and on which they reposed in good faith, and not passively, does not amount to forfeiture or abandonment.

lation to surrounding matter, a distinction between it and what is old, and well-defined claims, are all that can be required in a specification.

RESOURCES OF CALIFORNIA.—A new edition of the "Resources of California," the well-known work of reference written by Mr. John S. Hittell, has appeared. The new matter brings up to date all information concerning population, wealth, debt and taxes, railroads, manufactures, etc. The most important portion of the new material is comprised in a chapter on "pulmonary climatology." Mr. Hittell has compiled a great deal of useful and valuable information on therapeutical climatology which proves that the hygienic advantages of California were not exaggerated when our information was less accurate than at present. The tables of relative humidity of various places are also useful. This is the seventh edition of the "Resources of California," a book which is valuable to any one desiring information of any kind concerning this State, and which has, since the first edition, been looked upon as the only reliable work on the subject. The information on the various subjects is in a convenient form, and the skill of the compiler has enabled him to present his facts in a manner which renders them easy of reference.

THE Cerrillos mines of New Mexico, which are considered in New Mexico as the rivals of Leadville, increase in richness as the shafts are sunk. The lack of capital has caused much delay, which has been increased by the fact that the Atchison, Topeka & Santa Fe railroad is being built almost directly to the mines, and will reach there about December 15th, which has caused many to postpone active operations till then.

DEWEY & CO'S

SCIENTIFIC PRESS

Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free.

Address.

DEWEY & CO.,

ST. DAVID'S.

A FIRST-CLASS LODGING HOUSE.
CONTAINS 113 ROOMS.

715 Howard St., near Third, San Francisco.

This House is especially designed as a comfortable home for gentlemen and ladies visiting the city from the interior. N. dark rooms. Gas and running water in each room. The floor are covered with body Brussels carpet, and all of the furniture is made of solid black walnut. Each bed has a spring mattress, with an additional hair top mattress, making them the most luxurious and healthy beds in the world. Ladies wishing to cook for themselves or families, are allowed the free use of a large public kitchen and dining room, with dishes. Servants wash the dishes and keep up a constant fire from 6 A. M. to 7 P. M. Hot and cold baths, a large parlor and reading room, containing a Grand Piano—all free to guests. Price single rooms per night, 50 cts.; per week, from \$2.50 upwards.

R. HUGHES, Proprietor.

At Market Street Ferry, take Omnibus line of street cars to corner Third and Howard.

C. C. Bitner's Apparatus for Obtaining Metallic Copper from Its Solutions.

Patented March 18th, 1879. Will precipitate with steam in three hours, requiring no machinery to run it. Cost of constructing apparatus, \$75. The old cylinder process takes four hours to precipitate and costs from \$1,200 to \$1,500 to construct, besides a Grand Piano—all free to guests. Price single rooms per night, 50 cts.; per week, from \$2.50 upwards.

PHOSPHATE SOAP

THE BEST soap for toilet use ever manufactured. BEST because it contains all the excellencies of the most expensive foreign or American soaps without their defects. BEST because it combines strength with delicacy in such a way that its strong detergent qualities do not injure the skin. BEST because it is the result of years of study and experiment in the soap manufacturing business, assisted by modern chemical discoveries. BEST because it contains ingredients beneficial to the skin, which unite chemically with the soap in such a manner as to increase its saponaceous qualities. Every chemist familiar with soap manufacture knows that some ingredients which are in themselves beneficial to the skin cannot be saponified; some are partially neutralized, while others injure the quality of the soap. There are soaps in the market which are to some extent beneficial to the skin, but they are inferior articles for toilet use. PHOSPHATE SOAP is the ONLY article offered to the public which combines all the best elements of toilet soap with medical ingredients beneficial to the skin.

If your wife is in the habit of using cosmetics of any kind, advise her to give up the pernicious practice, as the most harmless face powders obstruct the pores of the skin and sooner or later injure the complexion, while PHOSPHATE SOAP removes all impurities and assists nature in developing a natural, healthy and beautiful skin.

It is an old proverb that an ounce of preventive is better than a pound of cure. Twenty-five cents invested in a cake of PHOSPHATE SOAP will save hundreds of dollars in doctors' bills. It acts as a constant disinfectant, preventing Salt Rheum and other skin diseases.

If your wife will persist in the use of cosmetics, buy her a cake of PHOSPHATE SOAP and tell her to use it every night before retiring. In that way much of the harm will be avoided, as the skin will thereby be able to retain much of its natural vigor and beauty.

No salve or ointment can heal a wound or sore of any kind. Every educated physician will tell you that nature alone can do this. PHOSPHATE SOAP, by its cleansing, soothing and purifying qualities, gives nature a chance to act freely.

Natural beauty surpasses anything which can be imparted by artificial means. PHOSPHATE SOAP gives health to the skin simply by removing impurities and eradicating the poisons which give rise to skin diseases.

Not only for daily use on the face and hands, but for bathing the entire body, there is nothing equal to PHOSPHATE SOAP. It is a thorough disinfectant and removes offensive odors of every kind.

Ladies who have injured the skin by the constant use of cosmetics may do much to restore their faces to that beauty which nature alone can give by constantly using PHOSPHATE SOAP.

For all diseases of the skin use PHOSPHATE SOAP. There is nothing like it for removing impurities and giving the skin a healthy and natural vigor.

Cheap toilet soaps manufactured from rancid and refuse grease injure the skin and are really more expensive than PHOSPHATE SOAP, which retails for 25 cents per cake.

Thousands of articles are palmed off on the public which have no genuine merit, but PHOSPHATE SOAP is the result of modern discoveries of celebrated chemists.

PHOSPHATE SOAP costs no more than other good toilet soaps, while its medicinal qualities make it worth ten times its price to every man, woman and child.

If you want a nice article of Toilet Soap and something that is beneficial to the skin, buy PHOSPHATE SOAP.

Metallurgy and Ores.

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

The use of Photography in producing stereotype and electrotype plates for artistic and common printing, forms, comparatively, a new method, in which we are making continual improvements and executing different kinds of work, superior to any before issued. It also enables us to produce certain kinds of work at greatly reduced prices.

Designing and Wood Engraving of every variety in the best style of the art, continued as usual. All orders executed promptly and on the most reasonable terms. We guarantee satisfaction. For the credit of our own journals, our customers can rely upon first-class work of the styles desired.

SCIENTIFIC PRESS ENGRAVING CO.,

GOLD AND SILVER

Grinding and Amalgamating MACHINERY.

Stamp Mills, Rock Breakers, Crushers, Rollers, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

SPERRY'S

Wrought-Iron Frame FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular. We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc. Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making the Machinery complete for a 10-Stamp Mill for the sum of

\$2,250.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

[CONTINUED FROM PAGE 213.]

every indication goes to show that this newly discovered ore body is of no mean dimension. A large number of assays range from \$72 to \$900, being the highest and lowest assays made up to that time. This ore has a little spar running through it, but the progress is made into the ore the spar disappears. Superintendent Gould is of the opinion that he has not struck the main ledge, but is getting close to it.

RAVENS & ELV.—The Superintendent says: We are taking out considerable ore from the 9th level, but it is low grade; on the 10th we are not taking out much; on the 11th the future prospect is very encouraging and have a good body of ore.

BELMONT DISTRICT.

BELMONT.—*Courier*, Sept. 27: The mine will soon be producing plenty of rich ore. Ore body south of shaft looks huge, and stone is getting larger every day. It is expected that this part of the mine will yield \$50,000. Ore bodies in ground north of shaft are more extensive than at first supposed.

SPRING VALLEY DISTRICT.

PLACER MINE.—*Star State*: Robert Pfleger informs us that the Little Bear placer mine, in Placer mining near the Eagle mine, in Spring Valley, frequently takes out an ounce of gold a day with a rocker. Water is very scarce at present, there being scarcely enough of that fluid to run a rocker steadily.

TUSCARORA DISTRICT.

INDEPENDENCE.—*Battle Mountain Messenger*, Sept. 27: The south drift on the 172 level has been extended 623 ft since the 5th inst., the ledge in this drift has varied in width from one to three ft, low grade chloride ore. An upraise will be started to-morrow to connect with winze from the 90 level. The ledge in this drift averages about three ft in width, carrying some rich ore, but the average is low. The vein in this drift has been made with the north winze, showing a continuous vein between the 300 and 400 levels, some portions of which is \$100 ore. The chloride estopes are not yielding as well as usual; ore, low grade.

BELLE ISLE.—The ledge in the 150 level, north drift, is increasing in size and the ore improving in quality. The lateral drift in the hanging wall vein, 150 level, has been extended for the week 12 ft. The vein will average 12 to 14 inches of rich sulphuret ore. The winze on the 150 level has been sunk 11 ft for the past week; have cut the ledge and are now sinking on an incline with the ore vein, which is 20 to 22 inches wide, of first-class sulphuret ore. The stopes are looking and producing well.

NORTH BELLE ISLE.—The north drift, 70 level, has been extended 10 ft on a vein of ledge matter interspersed with rich ore.

TUSCARORA M. & M. Co.—The ledge in the face of the tunnel is about 2 1/2 ft wide, from 6 to 8 inches of which is fine looking chloride ore, balance low grade.

CORNUCOPIA DISTRICT.

LEOPARD.—*Battle Mountain Messenger*, Sept. 27: Since the date of last report the connection between the 700 and 800 levels has been made and a good circulation of air obtained. The crosscutting on the 800 level is being advanced with all possible speed. We are extracting some good ore from the 700 stopes. Will start stopes from the 800 level as soon as the face of the main drift is far enough advanced. The mill continues to run on tailings and is doing good work. Will commence milling ore on the 1st prox.

AURORA DISTRICT.

RICH DISCOVERY.—*Bodie News*, Sept. 27: A rich discovery has been made in the rear of the old Real del Monte mill, in the upper part of the hill, where the ore, when one of them noticed a boulder having a mineral appearance, and impelled by the instincts which rule all prospectors, one of them broke off a piece of the rock. Our informant tells us that free gold was thickly interspersed through the quartz in such quantities as to eclipse in richness even the famous Bodie bonanzas. Further search resulted in uncovering a ledge three feet wide of rock similar to that described, and the news of the find was at once communicated to parties in Aurora. It is reported to us by a man whom we consider reliable, that the ledge, on examination, appeared so valuable that one of the men, whose name we failed to learn, accepted an offer of \$7,000 for his interest, and left on the evening's stage. The story comes to us so straight that we cannot doubt its truth, and, knowing, as all do, the immense richness of rock found in Aurora many years ago, we must believe that the long-sought ledge has been found at last.

PARADISE DISTRICT.

BULLION.—*Reporter*, Sept. 27: From a gentleman just down from Spring City, we are informed that a very rich streak of ore was struck in the Bullion mine a few days ago, and that that mine is now producing more ore than it has at any previous time. The Sedan mill is kept constantly running on Bullion ore.

ARIZONA.

NEW DISCOVERY.—*Expositor*: A Mr. Tilden came into Phoenix with several large pieces of what he thinks is rich argentiferous galena ore. On inquiring we were informed that Mr. Tilden discovered a vein of this ore which is 15 inches wide, about 20 miles north of Phoenix, near the Cave Creek country.

TOUJONVILLE.—*Tucson Citizen*: The Lucky Cuse has increased its working force and already a fine pile of ore is on the dump, which will be transferred to the new Corbin 20-stamp mill as soon as completed. From the quantities of rich ore in the camp it is safe to predict that, with the excellent mill of the Tombstone Co., and the new mills now in course of construction, Tombstone will be able to ship \$300,000 worth of bullion monthly.

CLONE DISTRICT.—*Star*, Sept. 27: The Nugget Co. are timbering their main shaft which is down 100 ft. When this is done they will crosscut the ledge and also sink another 100 ft and again cut the ledge. The same company have also another shaft down 60 ft on a spur which runs from the Mack Morris side ground and about 60 ft from the Mack Morris south line. It also shows good ore, silver glance, and will assay at least \$1,000. The pay streak is two feet wide. Ore from the Julian mine, worked in the Ishella mill gave a return of \$567.58.

COLORADO.

ACTIVE MINING CAMP.—*Georgetown Miner*: On Collier mountain, is the Modoc, with a 200 ft tunnel, yielding a large quantity of a fine quality of bismuth ore, which mill runs 700 ounces; also the Lancaster lode, with one tunnel 240 ft in length, and one 130 ft long, showing a crevice of 5 ft, a gray streak of 10 inches, assaying 140 ounces in silver. The Waterman lode, near the Modoc, contains bismuth of a very fine quality. The Fairview lode mills 300 ounces of bismuth ore. The Hannibal has a tunnel of 200 ft, showing a vein of lead from 13 to 24 inches, interspersed with gray copper. On Clenden mountain are the Woodchuck, Walker, Bell East and West, Hermann, Tiger Extension and St. Cloud lodes, all yielding a large quantity of a fine quality of galena, carbonate of copper and gray copper ore. The Walker lode is opened by a 200 ft tunnel and mills 400 ounces. Dozens of other good paying mines might be mentioned. All are being worked energetically. Messrs. E. C. Green and J. W. Suischer have just opened a fine prospect, the crevice of which is five ft wide, and galena is found through the entire width.

IDAHO.

NEW MINE.—*World*: The company that discovered the ledge at the head of California gulch, near Placerville, a few weeks ago, obtaining enormous prospects, are at work on it. They are stripping off the surface, and extracting the rock to a depth of a few ft. The vein is very narrow, being only from two to three inches wide, the ore decomposed and resembling sticky clay. It yields \$25 to the pound, of very coarse gold. J. W. Davidson & Co. own the south extension of it, on which they have a shaft down 22 ft. They have rich ore, but not as good as that in the location at the head of California gulch. Their shaft is

four ft wide, and has not come in contact with either wall. All the rock in it prospects.

ATLANTA CITY.—*Statesman*, Sept. 25: Mr. Kelly, the editor, recently visited the mines at Atlanta, and in a resume of his visit, says: At the Buffalo company's mill, one mile below town, we found some very high-grade ore from the Pilgrim mine, in the Alturas Lake district, ready for crushing. The mill is in excellent order, and well supplied with every facility for the speedy crushing of ore. At the Monarch company's mill we found Mr. Robinson busily engaged running the pans and concentrator on the rich tailings which have accumulated from former crushings. The Monarch company have discovered several good ore bodies in their numerous tunnels and crosscuts, and are now engaged in sinking a huge shaft of three compartments. The dimensions of the shaft are 10x7 ft outside the timbers, which are one foot square. It is the intention of company to continue sinking until the mine and running tunnels and crosscuts until their ground is thoroughly prospected and developed. About 500 tons of rich ore from the mine is under contract for crushing at the Buffalo mill. Peddler & Davis, the owners of the Tehama mine on Atlanta hill, have large quantities of good ore on the dump and in the chutes ready for crushing. This mine is well opened and shows a continuous body of good ore. George Sims, on the Moultrie and Jessie Benton mines (now consolidated) has struck rich ore on the upper levels, and will soon commence operations on a large scale. In the Alturas Lake and Wood River districts, very rich discoveries continue to be made; some of the veins rivaling in size and richness of the ore the far-famed Atlanta lode.

Solving the Debris Question.

A plan for disposing of the debris question, and preventing their accumulation, has been proposed by W. C. Schaffer, of Sutter county, of which the Colusa *Sun* says: He proposes to take the whole of the Yuba river, at ordinary stages of water, through a double flume, down into the low lands between the Yuba, the Sacramento and American rivers. Mr. Schaffer proposes a double flume, with rifles in each, for the purpose of running one of them at a time, and catching the fine gold. He thinks the gold thus caught would pay the interest on the cost of the flume, which he estimates at \$10,000,000. The flume as proposed will be 50 miles long, 100 feet wide, 8 feet in depth with a partition in the center. The entire Yuba river is to be run through this flume and the tailings deposited on the tule lands of Sutter county. The water in the flume will have a velocity of several miles per hour on a fall of one inch to the hundred feet.

The plan is an enormous one, and with amount of the estimate at hand could be accomplished. The *Sun* further says: Under this plan the whole basin, some 100,000 acres, would have to be condemned. The flume could then be carried to that part of the land nearest the foothills first, and that filled in, say 20 feet above the bank of the river, and then moved toward the river, making land as it went. It would take two or three generations to fill the whole in, but a great deal of good land would be made every year, which would help to pay for the flume. This debris land is, after a few years, fertile enough, but the trouble now is that it ruins the land by washing over it every year. Land built up after this manner we have suggested would not be subject to overflow, and in a few years would become good land.

In connection with the same subject, the Grass Valley *Union* says: There have been a number of suggestions as to the disposition of the mining debris, but there has been no engineering done to serve as an intelligent guide in providing a remedy. This prerequisite will soon be furnished, as State Engineer Hall, assisted by Col. Von Schmidt and J. F. Alhart, both able civil engineers, are now with a full corps of men making an instrumental survey of the South Yuba river, to ascertain its fall, the extent of washing and deposits, and to obtain such other information as will serve as a basis for formulating a practical plan for regulating the deposit of debris, in order, if possible, to make it useful instead of an injury to the low lands of the valley. The engineering corps has worked up as high as Purdin's Crossing of the South Yuba, on the Nevada and San Juan road, and it is understood that their survey will extend up the river as far as hydraulic mining is carried on at present, or likely to be in the future.

ENCYCLOPEDIA OF INDUSTRIAL ARTS.—Spon's Encyclopedia of Industrial Arts, Manufactures and Commercial Products, of which we made mention several weeks ago, has now reached its sixth part, and the publication fully justifies the promise of thoroughness and freshness of fact and style, which the earlier issues ontheld. Part V. continues the exhaustive treatise on the alkalis which began in the preceding part; 27 closely printed pages being devoted to potash. The treatment of this important substance, in all its points of derivation, manufacture and uses, is full and accurate, and well illustrated. There follow 33 pages of similar character on soda. The illustrated descriptions of the best processes of manufacture are among the clearest and most comprehensive ever written. Part VI. contains a group of important themes including alloys, amalgams, arsenic manufacture, assaying, atomic weights, aerated waters, beer, etc. The encyclopedia has already demonstrated its value as a source of information for manufacturers, the trade and the general reader, and we have no doubt this high character will be maintained. The work will be completed in about 30 parts, and will constitute in itself a condensed library of reference on industrial topics. The publishers are E. and F. N. Spon, 446 Broome street, New York city.

The free delivery postal system goes into effect at Sacramento on October 2d, with 5 carriers, 2 of whom will be mounted.

News in Brief.

GERMANY has sent a scientific mission to Africa.

A VICTORY has been achieved by the Bolivians at Coloma.

INDIAN troubles are again reported from Boise Basin, Idaho.

THE German quarrel with Japan is said to be getting more serious.

SCOTCH, English and Swedish farmers are emigrating to America.

IMPORTS of specie at New York last week aggregate \$8,557,542.

THE hop crop in England this season is the smallest since 1860.

ALL quarantine restrictions against New Orleans have been removed.

THE United States Supreme Court meets in Washington, October 13th.

CABUL is still in a state of anarchy, and the gates of the city are closed.

PORTLAND, Or., is to have a free postal delivery, commencing October 1st.

CARS are being run in New York now on schedule time by compressed air.

THE British troops continue to advance on Cabul, accompanied by the Ameer.

THE Mercantile Mutual Marine Insurance Co. of N. Y. has closed up its business.

SILVER in London, 51 1/2; consols, 97 15-16; 5% U. S. bonds, 106 1/2; 4s, 105 1/2; 1 1/2s, 109 1/2.

THE election of Sir Francis Wyatt Truscott as Lord Mayor of London is announced.

GERMANY will probably participate in the proposed International Money Conference.

GOLD and silver coin is hereafter to be paid out freely for all Government obligations.

DISTURBANCES are imminent at Tipperary, Ireland, in connection with the land troubles.

THE Russian expedition against the Tekke Turcomans is in urgent need of reinforcements.

THE Philadelphia mint coined in September: silver dollars, \$1,808,050; minor coins, \$14,737.

THERE is a scarcity in the Treasury at Washington of gold in denominations of less than \$20.

It is reported that 23 prospectors have been massacred by the Indians in southeastern Utah.

SPECIE in the Imperial Bank of Germany decreased during the past week 4,806,000 marks.

THE claim of the right to use the military roads in Bulgaria has been conceded to the Turks.

A GENERAL strike of all the trades in the United States and British North America is on foot.

A TWO days' fight took place in Texas recently between Indians and hunters, seven of the latter being killed.

AT Liverpool wheat is quoted at 9s 10d@10s 6d for averages California whits, and 10s 9d@11s 2d for club.

UNLESS there is some change soon, it is feared that the cotton industry in France will come to a standstill.

LEGITIMIST banquets were given at several places in France in honor of Count de Chambord's birthday.

THE excess of exports over imports for the year ending Aug. 31st, 1879, amounted to \$289,709,341.

THE walking match at New York ended last Saturday night, Rowell winning the belt—making 530 miles.

PINE tree cones, which contain the seed, are being exported in large quantities to Europe from British Columbia.

THE Public Stock Exchange of Todd, Williams & Co., at Philadelphia, suspended payment Sept. 30th. Liabilities, \$250,000.

Gold and Silver Products of Mexico.

It appears from the N. Y. *Economist* that the registered coinage of the Mexican mint, and statistics gathered by Baron Humboldt and other reliable authorities show the yield of her gold and silver mines, from 1521 to 1876, to have reached the sum of \$3,498,140,421. This array of figures indicates pretty clearly her capacities for bullion production. Some idea of prolific character of the mines and mining districts in that country may be gained from the following figures, denoting the yield in a few cases:

Biscuena Silver Mines.....\$ 10,341,000
Santa Ana " ".....21,347,210
Valeneta " ".....31,813,480
Rio Grande District.....650,000,000
Sierra Madra ".....800,000,000
Veta Madra ".....335,335,730

The Panilian silver mines produced \$20,000 per diem for five years, when operations were stopped by a flood of water. After being opened again, it produced in ten years \$40,000,000.

It again laid idle until 1871, when work was once more resumed, and an annual yield realized of \$13,400,000, making a grand total of nearly \$100,000,000. All this vast amount of gold and silver was extracted from the mines of Mexico by the most crude and primitive modes and appliances, of which no better idea can be obtained than by contrasting their results with those produced by modern improvements.

The miners of the Pacific slope have accomplished, in thirty years, two-thirds of what the miners of Mexico accomplished in 355 years, i. e., since the conquest of Mexico by Cortez. There is no question as to the great number, extent, and richness of the mines of Mexico, and when they come to be worked by the improved machinery and appliances of to-day their yield will be proportionately greater.

PATENTS AND INVENTIONS.**List of U. S. Patents Issued to Pacific Coast Inventors.**

m Official Report for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.]

FOR THE WEEK ENDING SEPTEMBER 23d, 1879.

219,912—AMALGAMATING PAN—Extra Coleman, S. F.
219,913—MULLER FOR AMALGAMATING PAN—Extra Coleman, S. F.

219,942—CARPENTER'S GAUGE—A. Helran, San Leandro.
219,985—BUNG—W. D. Scott, S. F.
219,998—ANIMAL TRAP—W. J. Taber Wyoming Ter.

219,837—PROPELLER FOR VESSELS—Geo. Vincent, Stockton, Cal.
7,691—BREAD-RISING PREPARATIONS—Trademark—B. Y. Barton, S. F.

7,692—YEAST POWDER—Trademark—D. Callaghan, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

PROPELLER FOR VESSELS.—George Vincent, Stockton, Cal. No. 219,837. Dated Sept. 23d, 1879. This invention relates to certain improvements in the construction of propellers for vessels; and it consists in a novel formation of the blades, which are made of plates having a plain flat surface, standing at an angle with each other, and also with the line of the axis.

The usual method of forming propellers is to make them with two, three or four blades, having the curve and pitch of a screw; but in this invention blades are employed which are in the form of flat plates, having no curve at all. These plates are fitted up to the hub, so as to stand in a plane, which crosses the axis at an oblique angle. This angle may be varied to suit the work for which the propeller is designed. The propelling force will be superior to that of a regular screw, for the reason that the blades, being perfectly plain instead of being curved in section, certain unfavorable conditions due to this curvilinear form are avoided, so that while the best effects of the screw are produced when the blades are made quite narrow, this propeller will produce its maximum effect when the blades are in the form of sections which occupy nearly or about one-half of the circle which they appear to produce when viewed in a line with the shaft, the outer ends of their enclosing radial lines being cut by the lines forming the obtuse angle.

ORE FURNACE.—Georgs W. Reamer and Edward Anderson, Forest Hill, Placer county, Cal. No. 219,763. Dated September 16th, 1879. This invention relates to an improved furnace for roasting and desulphurizing ores, and it is more particularly intended for working the ores of mercury, the fumes of which are to be caught and conveyed to condensers. It is specially constructed to roast fine ores, which, in ordinary furnaces are apt to clog or liable to pack in such a manner that the fire has not free access to all the particles. It consists in constructing a central chamber between vertical walls, on the outer side of each of which is a fire-place, the drafts from the two fire-places passing in opposite directions and meeting in a common flue, where they join the fumes from the ore and pass to the condensers.

LATH SAWING MACHINE.—Josiah Black, Oakland, Cal. No. 219,678. Dated September 16th, 1879. This invention relates to that class of wood-sawing machinery such as is used for sawing out laths, and the improvements consist in providing a moving table, on which the saws are placed, while the log remains stationary, only feeding forward enough for a new cut of the saws. It also relates to a method of mounting the saws, so that some of them may be thrown out of action if desired, and to certain details of construction, whereby the feed of the log is accomplished automatically.

CARBURETER.—Mark P. Fleming, Oakland, Cal. No. 219,705. Dated September 16th, 1879. This device relates to an improved carbureter for enriching gas or air; and consists in certain details of construction for catching and discharging the water of condensation, and by means of which the gas or air is thoroughly saturated with the enriching hydrocarbon oils.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Gold Hill (L. T.), Sept. 24th, \$27,834.86; Northern Belle, Sept. 22d, \$4,442.72; Hillsdale, Sept. 25th, \$6,000; Alexander, Sept. 25th, \$7,162.11; Northern Belle, Sept. 24th, \$4,528.96; Belle Isle, Sept. 28th, \$14,700; Independence, Sept. 28th, \$2,100; Hillsdale, Sept. 29th, \$6,000; Bodie Con., Sept. 29th, \$20,500; Martin White, Sept. 28th, \$5,224.54.

William Hawkins,

(SUCCESSOR TO HAWKINS & CANTRELL.)

MACHINE WORKS,

210 and 212 Beale Street, bet. Howard and Folsom Sts., - - San Francisco.

Manufacturer of

IMPROVED PORTABLE HOISTING ENGINES,

FOR MINING AND OTHER PURPOSES.

Also of the HAWKINS' PATENT ELEVATOR HOIST, for Hotels, Warehouses and Public Buildings.

Steam Engines and all Kinds of Mill and Mining Machinery.

Fulton Iron Works.

Hinckley, Spiers & Hayes.

(ESTABLISHED IN 1855.)

Works, Fremont and Howard Sts. | San Francisco, Cal. | Office, No. 213 Fremont St.

MANUFACTURERS OF

Marine Engines and Boilers,

Propeller Engines either High Pressure or Compound Stern or Side Wheel Engines.

Mining Machinery.

Hoisting Engines and Works, Cages, Ore Buckets, Ore Cars, Pumping Engines and Pumps, Water Buckets, Pump Columns, Air Compressors, Air Receivers, Air Pipes.

Mill Machinery.

Batteries for Dry or Wet Crushing, Amalgamating

Engines and Boilers

of all kinds, either for use on Steamboats and made in accordance with the Act of Congress regulating the same, or for use on land. Water Pipe, Pump or Air Column, Fish Tanks for Salmon Canneries of every description.

Boiler repairs promptly attended to and at very moderate rates.

Pans, Settlers, Furnaces, Retorts, Concentrators, Ore Feeders, Rock Breakers, Furnaces for Reducing Ores Water Jackets, Etc.

Sugar Machinery.

Crushing Rolls, Clarifiers, Vacuum Pans, Air Pumps, Concentrators, Bag Filters, Charcoal Filters, Blow-up Tanks, Coolers and Receiving Tanks.

Miscellaneous Machinery.

Flour Mill Machinery, Saw Mill Engines and Boilers, Dredging Machinery, Oil Well Retorts, Powder Mill Machinery, Water Wheels.

Pacific Rolling Mill Co.,

SAN FRANCISCO, CAL.

MANUFACTURERS OF

RAILROAD AND MERCHANT IRON,

ROLLED BEAMS, ANGLE, CHANNEL AND T IRON, BRIDGE AND MACHINE BOLTS, LAG SCREWS, NUTS, WASHERS, ETC., STEAMBOAT SHAFTS, CRANKS, PISTONS, CONNECTING RODS, ETC., ETC.

Car and Locomotive Axles and Frames, and Hammered Iron of Every Description.

HIGHEST PRICE PAID FOR SCRAP IRON.

Orders Solicited and Promptly Executed.

Office, No. 16 FIRST STREET.

PACIFIC IRON WORKS,

First and Fremont Streets, between Mission and Howard, San Francisco, Cal.,

RANKIN, BRAYTON & CO.,

Manufacturers of

ENGINES, BOILERS, MARINE AND STATIONARY. PUMPING, HOISTING, AND MINING MACHINERY INCLUDING BATTERIES, AMALGAMATING PANS AND SETTLERS, CONCENTRATORS, ORE FEEDERS, CRUSHING ROLLS AND ROCK BREAKERS. ALSO, WATER JACKET SMELTING FURNACES, FOR REDUCING LEAD, SILVER AND COPPER ORES, QUICKSILVER FURNACES, RETORTS AND CONDENSERS, ROASTING AND CHLORIDIZING FURNACES, SUGAR-MILL MACHINERY, WATER WHEELS, ETC., ALL OF THE LATEST AND MOST IMPROVED CONSTRUCTION.

Agents for the Allen Engine Governor, Bailey Air Compressor, Howell's Improved White Furnaces, Walker's Compound Steam Pumps, Etc.

Union Brass Foundry,

And Mechanical Workshop.

Manufactures all kinds of Brass Goods, Plumbing, Brewery and Distillery Work, Gas and Soda Apparatus, Mining Goods, Ship Work, Steam Fittings, Water Gates and Valve Meters, Gauges, Counters, Indicators, etc.

MACHINE PATTERN and MODEL MAKING a Specialty. Bell and Brass Castings to order at shortest notice. Clock Work Gears cut to order. Highest Market Price paid for Old Metal. For particulars and price lists address

GIOVANNINI & CO.,

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Captains, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER.

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens often rely on contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

Main Street Iron Works,

WM. DEACON, PROPRIETOR.

Nos. 131, 133 & 135 Main St., San Francisco.

Stationary and Marine Engines,

Shafting, Pulleys, and General Machine Work. Jobbing and repairing done Promptly and at Lowest Rates. Screw Propellers, Propeller and Steamboat Engines.

SAW MILLS and SAW MILL MACHINERY.

A CARD.

To Parties Interested in Mining and Milling.

Call at J. HENDY'S, N. E. corner of Mission and Fremont Streets, San Francisco, and examine COLEMAN'S PATENT SLUICE. It will save both float and flour Gold. The best system yet devised. No power required to work it. Examine it and judge for yourselves before purchasing elsewhere.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

GOLD MINE WANTED.

One now paying more than expenses. Address

W. S. KEYES, M. E.

No. 310 Pine St., Room 42, San Francisco

Good land that will raise a crop every year. Over 14,000 acres for sale in lots to suit. Climate healthy. No droughts, bad floods, nor malaria. Wood and water convenient. U. S. Title, perfect. Send stamp for illustrated circular, to EDWARD FRISBIE, Proprietor of Reading Ranch, Anderson, Shasta County, Cal.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot, PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

FRASER & CHALMERS

STEAM ENGINES, BOILERS, STAMP MILLS, FRIE VANNERS
(and Machinery) for Systematic Mining, Milling, Smelting and Concentration of Ores.

No. 145 Fulton St. CHICAGO, ILL.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street, San Francisco, Cal.

FRANCIS SMITH & CO.,

Manufacturers of

THE PATENT CHANNEL IRON WHEELBARROWS.

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

From 1-4 to 10,000 lbs. Weight.

True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three fold strength. Gearing of all kinds. Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc. 12,000 Crank Shafts of this steel now running proved superior to wrought iron. CRANK SHAFTS, CROSSHEADS and GEARING, specialties. Circulars and Price Lists free. Address

SHEET IRON PIPE.

RUSSELL'S AMALGAMATOR.

Patented June 25th, 1878.

SAVE YOUR GOLD

And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 80 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

No. 653 and 655 Mission Street, San Francisco, Cal.

EDWARD G. DENNISTON, PROPRIETOR.

Dunham, Carrigan & Co.,

Nos. 107, 109 & 111 Front Street, S. F.

Lathe Without Saw Attachments.

This lathe has been made especially to meet a want felt by many for a really good and substantially made Foot-Lathe at a reasonable price, and we think that we can safely say that it is by far the best lathe ever placed on the market at the price asked. The bed, head, and tail stocks are of cast iron, and the head stock is conical, so that the wear can be easily taken up.

Material fifteen inches long and eight inches in diameter can be turned upon it. The pieces that accompany this lathe without extra charge are two 1 reeds, two paint-centers, one spur center for wood turning, and one face plate.

Price of Lathe without Saw Attachments.....\$45. Price of Lathe with Scroll Saw Attachment.....\$55
Price of Lathe with both Scroll and Circular Saws, \$70.

Trump Drill Chuck.

Chuck for drills $\frac{1}{8}$ and under,
Price.....\$1.50
Chuck, for drills $\frac{1}{4}$ and under,
Price.....\$2.25
They are made on solid steel
plugs, centered and readily fitted
to Lathe or Drill Press.
SEND FOR CIRCULAR.

VULCAN BLASTING POWDER.

The Strongest, Safest, Most Uniform and Reliable "HIGH EXPLOSIVE" Manufactured on the Coast.

MINERS TESTIFY THAT IT IS FREE FROM OBJECTIONABLE FUMES.

We call the attention of all desiring such a Powder to our various grades, which are prepared to sell at LOWEST RATES.

- No. 1. Equaling Liquid Nitro-Glycerine in Strength. We recommend this Grade in extremely hard rock, boulders, iron, etc.
No. 2. Will do the work thoroughly in all but the hardest kind of rock.
No. 3. For bench work, pipe-clay, soft and shelly rock, outside work and quarrying.
Single and Triple Force Caps, Fuse of all Grades, Vulcan Powder Thawing Boxes, Batteries and Exploders, For Sale at the Lowest Rates.

VULCAN POWDER COMPANY,

Office, 123 California Street, Rooms 25 and 26, - - SAN FRANCISCO, CAL.

Stronger, Better and Safer than any other High Explosive.

Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. **337 Triple Force Caps and all Grades of Fuses.**

BANDMANN, NIELSEN & CO.,

SAN FRANCISCO, CAL.

HYDRAULIC GRAVEL ELEVATORS,

For working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

JOSHUA HENDY,

No. 51 Fremont Street, Office of the Hydraulic Gravel Elevating Mining Co., S. F.

Howland's Under-current, Mill and Sluice Riffle.

This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from flouting or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

ALLEN GOVERNOR.

This Governor is now being generally adopted throughout the United States and Europe. It is without doubt the

Most Perfect Engine Regulator in Use, And will in most cases save its cost several times a year. It is invaluable on a QUARTZ, FLOUR or SAW MILL ENGINE, or in any Manufacturing Establishment, where Regularity of Speed is desirable. By being able to run the engine to its full capacity, these Governors have in many cases added

Ten Per Cent. to the Productive Capacity of a Mill,

Thus saving more than their cost every week in the month. Every Engine to which this Governor is attached will run with the throttle wide open. The speed of the Engine can be changed by a simple adjustment of the weights. It will give a UNIFORM SPEED WITHOUT REFERENCE TO THE BOILER PRESSURE. It is simple in construction and not liable to get out of order.

Every Governor warranted to give perfect satisfaction. Thirty days given for a trial, and if it does not fulfill all that is promised, it can be returned at our expense.

In ordering, state the kind of engine, diameter of cylinder, stroke, speed, and average pressure.

Send for full descriptive circular.

RANKIN, BRAYTON & CO.,

Geology of the San Jose Mining Co.'s Mines.

The property of the San Jose mining company is at Egan canyon, White Pine county, Nevada, and consists of some seven consecutive mines on the ledge, aggregating 7,015 feet, and 6,000 feet more of other mines in the northwest and northeast. Egan canyon is in Gold Canyon district, about 90 miles south of Wells' station, on the C. P. R. R. Near the creek in the canyon is the company's 20-stamp mill, with an engine sufficiently powerful to drive 40 stamp. The company was organized in 1871, and more or less work has been done on the different mines since then; but great difficulty was met with in the water, and a tunnel had to be run to draw it off. General Rosecrans was the engineer in charge for some time, and is now President of the company. The other trustees are W. H. McCormick, A. Carrigan, M. J. O'Connor and T. H. O'Connor.

A report made by Prof. J. E. Clayton on this property is interesting, as showing the geology of this section of country. We condense as follows from his report:

The geological formation is composed exclusively of the oldest stratified rocks, in alternate zones of schist, quartzite and slate, aggregating a thickness from east to west of about 10,000 feet, including the entire series of beds between the Azoic and Paleozoic formations.

The upheaval of the beds has been from the east towards the west, and their upturned edges form the entire east face and summit of the Egan range. The west flank of the range and the high ridges west of the Egan basin are made up of the silurian, devonian and carboniferous beds, consisting mainly of calcareous shales and limestones peculiar to those geological ages.

The section and diagram annexed, give from east to west across the range the order of occurrence of these geological formations.

The strike of the beds, or strata of the country rock, is nearly N-S; dip of the beds towards the west, at angles from 40 to 80 degrees.

The quartzite is hard, vitreous and fissile, in parts much broken and crushed by geological disturbances. The slates are tough, usually fine texture, finely laminated, with fracture lines oblique across the stratification, giving it a jointed appearance. The Gilligan lode cuts obliquely across the country rock, from S. W. to N. E., and the dip is N. W. at angles varying from 50 to 80 degrees below the horizon, the average dip being about 70 degrees. The lode varies greatly in thickness between its walls as well as in its mineral contents.

Where it passes through zones of slate, the vein gangue is made up of fragments of slate and clay, resulting from the abrasion or grinding of the walls during the period of disturbance immediately preceding the mineralization of the lode. In some places the fissure is filled with this ground-up clay and slate, to the exclusion of quartz and ore. Where the lode passes through the zones of quartzite the walls

are rougher, but still well defined. The fissure is more free from the debris of the walls, the vein usually larger and better filled with true quartz gangue and larger quantities of good ore.

The obvious result of this alternating of slate and quartzite is to divide the lode into pay chutes, or chimneys, and pinches or barren spaces between them. The evidence is seen in the "pitch" of the ore chutes to the west, conformably with the dip of the country rock. Hence we may expect to find the largest and most productive ore chutes where the walls of the lode are quartzite, and more pinched and unproductive where it passes through slate belts.

Taken as a whole, the Gilligan lode is a good example of the "true fissure" lode, of great length and undoubted persistence in depth. It is not a large vein, neither is it likely to become such in depth. It will probably enlarge

and dip parallel with those above described) that carries the vein a few feet south of its true course. The level, being continued on its course, missed the lode, and was driven in the hanging wall country a distance of 386 feet. The latter portion of this distance the level has curved to the south, cutting the lode 62 feet from the old Gilligan shaft. This of course has only exposed the lode 114 feet in a distance of about 500 feet. * * * The lode is, in all probability, richer in the precious metals below the permanent water-line than it is above it, owing to the well-known tendency of silver sulphurets to oxidize and become soluble. If chlorine be present in sufficient quantity, the soluble sulphate of silver becomes "fixed" as an insoluble chloride; but if chlorine is not present, the silver would be leached out by the surface waters and lost. Even if chlorine were present, it would not combine with the silver unless the mechanical conditions were favorable.

1st, by wearing down the canyon bed; and, 2d, an earthquake shock, breaking the strata, and loosening all the joints and seams in the country rock, thus suddenly shifting the drainage-line some hundred feet lower and leaving a corresponding zone of the lode undisturbed by the underground water flow.

If the foregoing statement of facts and suggestions are correct, it readily explains why rich blocks of ground in the ore chutes were found near the surface, and why the same ore chutes were impoverished near the present water line.

From a careful study of the facts and conditions present at various times in the geological history of your mines, I am strongly impressed with the correctness of the theory of the impoverishment of the ore chute near the water line and that the average richness of the lode is greater below the horizon of moving waters than it is above it.

The most notable instances supporting this view that I have studied are: 1st, the Atlanta lode in Altura district, Idaho; and 2d, the mines in Butte district, Montana.

In these two localities the fact of impoverishment by the action of the surface waters and atmospheric oxidation are unmistakable; and I can find no mechanical, chemical or other physical cause to prevent a like result in your mines. At any rate, if this is not the true solution of the facts and phenomena found in the Gilligan lode, I must confess my inability to solve the problem.

Notwithstanding my strong conviction that the lode is generally richer below the zone of surface drainage, I think the work of sinking to the deep should be deferred until after the lode above the drain level has been thoroughly explored and its paying ores made available. You must economize in the general business management, and devise more economical and efficient methods of ore reduction. Everything in the lode above

GEOLOGY OF MINES IN EGAN CANYON, NEVADA.

and contract alternately towards the deep, as we know it does on its horizontal course.

The large adit is well situated for the convenient exploitation of the lode, and is indispensable as a drain level and roadway into the mine. The work has been well planned and executed up to the intersection of the lode. Levels have been driven to the right and left on the course of the lode. The level to the right or N. E. extends some 600 or 700 feet, following the vein part way through slaty, pinchy ground 200 or 300 feet, then a series of cross courses and broken ground was encountered, making it somewhat difficult to distinguish the lode from the cross courses that cut the lode obliquely from S. S. W. to N. N. E. The dip of the cross courses or breaks is to the S. E., thus crossing the lode obliquely both on the longitudinal and vertical lines. At the last of these faults the level left the lode and followed the line of fault some 20 feet or more, then turned to the right upon the general course of the lode, but in the hanging wall country north of it.

The level S. W., towards the old Gilligan shaft, followed the vein 52 feet, then a wide cross course was encountered (having a course

For example, if the country rock were close like granite or porphyry, the water would stand in the lode at rest, except perhaps a slow movement down the line of fissure. In such case a very small quantity of chlorine would be sufficient to change the sulphate to a chloride of silver. No such conditions are to be found in your mine.

The country rock is hard, metamorphic sandstone (quartzite) and slate, very brittle and fissile, allowing the surface waters to pass through rapidly, thus diluting the solutions beyond the precipitating point, or carrying them away mechanically by the rapid movement of the waters.

The drainage line has been governed to a great extent by the grade of the canyon. There has been a time when the water-level was far above the present line. In the meantime the canyon has been plowed out from the edge of the valley back into the mountain, making a series of cascades over obstructing reefs. As these became broken down by the vast floods accompanying the geological disturbances at the close of the tertiary age, accompanied by crashing earthquake shocks, we can readily see that many sudden changes of water level occurred:

the drain level that carries ten dollars per ton should be extracted and worked with a margin of profit.

NEW ZEALAND GOLD FIELDS.—Late advices from New Zealand, per *Thames Advertiser*, indicate an improvement in the mines. The water is rapidly lowering by the working of the Big Pump. The result of a fortnight's run in the Moanatairi mine, with 20 head of stampers on 270 tons of quartz was 322 ounces of melted gold. Selected quartz from the old Welcome section of the Welcome extended yielded nearly six ounces of gold per ton. The result of 115 tons of quartz from the Kuranni Hill United was 745 ounces 11 pennyweights of gold.

The valleys, through which passes the rail road from Vera Cruz to the city of Mexico, are from 3 to 30 miles wide, bounded by steep mountains. Every part of this region is now under a high state of cultivation, and artificially irrigated in the best manner.

It is probable that Mexico will oppose De Lesseps' Panama canal scheme.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

The Mines of Pioneer District, Arizona.

EDITORS PRESS:—There are in this district, one of the most noted in Arizona, two distinct, but adjacent formations, in which the silver-bearing veins are found. Of these the easterly one was the first to attract general attention and claim to some extent the confidence of Nevada prospectors and experts, as its characteristics are similar to many of the most favored districts of that State. The country rock is gneiss, and the strike of strata northerly and southerly. The veins are generally of fair size and good definition, and the ores, though more encumbered with base metals, may be likened to those found about Austin, in the Reese River country.

The extent of this formation is not, and probably never will be, known, as its southern extremity finds its way beneath the overlying basalt, which, it appears, at one time covered the surface of this part of the territory for many miles in extent, and it is only at points where it has been broken down and carried away, exposing the country beneath it, that any metal-bearing veins are found at all. Its extension northerly remains to be determined by the prospector, but we know that for a distance of several miles north from the noted Silver King, which lies close to the *peache* or basaltic bluff to the "Surprise mine," which has yielded considerable fine ore, that the country is thickly laced with veins of more or less value. Of these the "Alice Bell," and one or two others, are showing good faces of ore—not because they were any better from the start than many others in the same section, but because they have been handled with some degree of energy and perseverance. These mines require a little means to open them in good shape, but they are mostly located and held in idleness by impecunious persons at figures which moneyed men very properly decline to pay.

The Silver King.

Although it has been stated that the mines of this locality are usually well-defined, this bonanza chief of the district is an exception to the rule, and has given rise to much discussion as to its probable course and permanence. Were it known to be a true fissure vein, a great impetus would be given to the prospecting of others belonging to the same formation, and its condition and peculiarities are therefore matters of public interest. The prospecting that has been done thus far in the immediate vicinity of the Silver King encourages the belief that, though quite extensive, it is only an isolated deposit and not a continuous vein of ore. Shafts sunk both in the North and the South Silver King, on the line of stratification of the gneiss, developed only a few thin and insignificant strata of ore. The owners, however, are sinking a new working shaft, which would indicate that they, at least, have confidence in the pay chute continuing in some direction.

Lying west and touching the gneiss formation above mentioned is one of limestone likewise found to contain much silver in veins not so well defined. The denudation of the basaltic rock has here been such as to expose a large belt of limestone averaging two miles in width and of indefinite length, and still affording opportunities for such prospectors as do not require a brand new district, and are willing to work with perseverance. The veins on this belt have several characteristics which render them especially interesting to scientific miners, and somewhat of a puzzle to experts, some of whom look upon them with enthusiastic favor, and others turning away in disgust pronounce them a fraud. The truth is no doubt between these extremes. The veins crop out only at points where they are capped with the black oxide of manganese which appears to resist the action of the elements. These croppings have commonly been mistaken for hematite, an oxide of iron which they somewhat resemble. In places where this hard cap is wanting, the ores sometimes appear at the surface or are only covered by a few inches of loose drift; and referring to such spots, a newspaper correspondent some time since stated it could be kicked out of the ground anywhere. The enormous disproportion between the price of shoe leather and the amount of ore so obtained, has prevented the adoption of the "kicking" process, yet it is a fact that on many of the locations, enough fine ore is found on the surface to place them beyond the necessity of soliciting capital to aid in their development—a very fortunate circumstance for the prospector.

It is admitted as a rule that ores found in limestone lie in pockets and hunches, and this is not claimed as an exception; but where these deposits are large and frequent, and always connected by leaders of gangue, mining for them may prove quite as profitable as though the ore bodies were continuous but narrower or of lower grade. To find large quantities of paying ore is the problem in mining, and it makes but little difference what shape it lies in.

The fact that this belt abounds in fine specimens, and the tendency of interested parties to elect only each for assay, has given rise to the

erroneous belief that its ores are wonderfully rich. The sooner such an impression is discarded the better, as it will not do on which to found any practical and successful operations. This limestone formation has never produced more than five or six tons of ore that would average over \$300, and none in quantity assaying above \$500 per ton, though it is not uncommon to find specimens which run well up in the thousands. The district can never look to fancy grade ores for success, and might better come down at once to sober facts and the consideration \$75 ore which is a very close approximation to the average value of that which can be produced in large quantities, enough at any rate to warrant the investment of capital and satisfy any reasonable expectation of profit. This assertion is not based on the hypothesis that the veins will be permanent, but is made on the strength of surface deposits already in sight. Their permanence is a question still shrouded in doubt, as no deep prospecting has yet been done but by theories and observations, too complex and numerous here to elucidate, the writer is led to the opinion that at a depth of several hundred feet they will assume more regular and definite shape.

Picket Post, September 20th, 1879.

Working Gravel Mines at Smartsville.

EDITORS PRESS:—The mines at Smartsville carry considerable quantities of black sand of high grade, an assay by Messrs. Frederick & Soderling, of Bodie, having indicated \$322.67 per ton, gold, including a small percentage of silver and 61-100 of 1% of platinum. The platinum appears in minute white particles, being generally very fine. The miners there knew that it is neither gold nor quicksilver, and that is about all they appear to know about it. I fear, however, that the quantity is not sufficiently large to prove of much benefit to Edison in advancing the electric light business. Up to this time but very little of the black sand has been saved, the miners generally being in too great a hurry to bother with these small matters, consequently much gold has doubtless been lost. These sands can only be saved in any considerable quantity by appropriate machinery. Several devices purporting to effect this purpose have been brought before the public. Miners should, therefore, investigate them, and if practical, give them a trial.

One great difficulty that has heretofore stood in the way of the erection of appropriate machinery was the lack of water suitable for motive power, the general impression appearing to have been that the muddy water as it flowed from mines could only be utilized for an overshot or some similar wheel. The cost of these wheels was such as to generally deter people from their use, and especially as but few sites would admit of their erection without a considerable expenditure for excavating or blasting.

Water from the mines, for motive power, on small wheels, may be made practical by means of a sand-settler, about 6 feet deep, 6 feet broad, and 12 feet long, the muddy water being made to answer an excellent purpose for driving small wheels by means of a chute, under pressure of a head of 20 feet or more. The mouth of the chute, or trunk, should be made of cast metal (preferably white metal, by reason of its great hardness), the wear from the grit left in the water being mostly on the chute. The sand should be drawn off at the bottom by means of two cast iron chutes about 3 inches square, having metal on 3 sides, the upper sides being open for the working of small gates. It is best to have two chutes for the discharge of the sand, as in case one should become stopped with a stone or some similar substance, one would still be open. The water intended for motive purposes should flow out at the top, and thence be conducted into a penstock, from whence it is discharged at the bottom.

My wheel at Gold Run is 5 feet in diameter, chute 2x4 inches, head of water 22 feet, discharging about 25 inches of water. The wheel was of my own get up, combining, to a considerable extent, the turbine principle, and gives splendid power. It ran nearly constantly, day and night, for about four months the past season in propelling my agitating device, and there was but very little wear of the chute or wheel. After the buckets become too much worn, which would probably not occur sooner than after 12 months of constant use, they can be very easily replaced with new ones.

The construction of a wheel similar to the foregoing, if there are good facilities, will cost, including irons, about \$32. It is, therefore, far cheaper and more practical than either an overshot or breast wheel for propelling any machinery that may be necessary to be erected in hydraulic mines for the purposes aforesaid.

I should have observed that, in order that the water for motive power may be as free from sand and stones as possible, it should be taken out near the top of the flume, and at a point sufficiently high above to give the desired fall at the place of erection. If there is but little fall in the vicinity, it will be necessary to take water some distance above in order that the desired fall may be gained. Thus, most flumes are built on a grade of from six to eight inches in 12 feet. The small sluice-box need not, at the outside, have a grade of more than two inches in 12

feet, and particularly if some of my concentrator irons, or other appropriate means, be used soon after the water is discharged from the flume into the small sluice-box for the purpose of freeing the water from sand. You thus gain from four to six inches in every 12 feet, and would not have to proceed very far before the small sluice-box would be sufficiently high above the flume to give the desired pressure.

As regards sulphurets, I will state that any practical device that will take black sand will also take them and other subtenances of value.

BRYAN TYSON.

Lake District, Mono County.

EDITORS PRESS:—The mines of Lake district are steadily gaining ground. Mammoth, the principal mine opened, have been building their mill of 40 stamps for the last three months, which is now completed and running steadily. Soon a steady flow of bullion will be the result. I examined, with Superintendent Hardy, the mine, and found everything in order. This mine is being steadily developed, with great improvements in their ore vein as they go south. Their mill will require 100 tons per day, which is easily extracted. This property is under the care of Col. Wm. Hardy, a man that means business, and is placing everything in first-class order. McClellan, the foreman, understands his business fully, and is the right man in the right place. The officers of the company are our most energetic men, well known in San Francisco. This mine is now entering on a new era, and is now worked and run in a very economical manner, and soon will be placed among our dividend mines. Work is being pushed on True Blue mine, and soon their vein will be opened by tunnel at a depth of 400 feet vertical. This company means business, and have bought 80 acres of land at foot of mountain to place their mills upon, and soon another mill will be added to the number. This mine has a large amount of ore on croppings, which shows assays from \$20 to \$1,000 per ton. I have seen no such croppings outside of Comstock mines, and they resemble them much. Ores are free milling. Don Quixote, adjoining True Blue, are also running tunnels, and will cut vein about the same depth as True Blue. This company has a fine property, which soon will be opened. Their ore is of a high grade; their vein will average 15 feet all pay ore. Headlight is doing nothing at present, but have joined Monte Christo in running tunnel, which will cut vein 600 feet vertical. Monte Christo is sinking shaft now 160 feet; their vein carries free gold, which runs into silver as depth is obtained. This vein is 13 feet wide, with good walls and shows a true fissure.

Another very rich mine has just been opened on the south end of belt called the Metallic Con. Free gold can be seen in the rock. The vein is about six feet wide, and is all pay; quartz is of a fine quality. Further developments will place this mine in a prominent position.

Lake View mining company, Judge Heydenfeldt, President, has a fine property, and lies on west side or slope of Mineral hill. The company own four mines in their incorporation. The ore is mostly silver. The North Star is their main location, and the second location in the district. Their croppings are immense, and if developed at depth this company would have an abundance of ore. They have a fine mill site and privilege at base of mountain, with wood and water in the greatest abundance. This company has a bright future.

There are other mines in this district that are briskly at work running tunnels and shafts to open up their veins in a prominent manner, and soon the mines of Lake district will be better known. The mines are permanent and lasting, and will soon employ thousands of miners. The future outlook of this district is indeed great.

A. CALDWELL.

Mammoth City, Cal., Sept. 26th.

MINING UNDER-CURRENT ON BEAR RIVER.—The Grass Valley Union says Wm. H. Kinder, of Gold Run, Placer county, has nearly completed an extensive "under-current" on Bear river, at a point a short distance below the Crandall road crossing, for the purpose of washing the mining tailings that flow down the head of the stream and extracting the fine gold therefrom. To effect this a substantial dam has been built across the river, which is high enough to give the tailings a fall into the sluices and under-current which are placed on the east bank of the river above flood mark. The sluices will carry off the heavier tailings while the fine particles will drop through the interstices of the sluices into the under-current, which has a broad surface of riffles and is charged with quicksilver. A mining arrangement of this character is to a great extent self-operating, and the under-currents are generally cleaned up but once or twice a year. This is the first under-current placed on Bear river to collect the fine gold that is known or believed to be carried into the stream from the hydraulic mining operations carried on in the neighboring districts on each side of the river. This plan has been tried successfully in other districts on a smaller scale, and it is thought that it will be found profitable when applied to Bear river, as it will take the washings of all the claims that are running tailings into it. The cost of the works will be about \$7,000.

Recent Discovery in Tuolumne County.

On September 27th, says the *Independent*, Wells, Fargo & Co. shipped from Sonora several hundred pounds of gold bars, the product of a mining claim in town. All kinds of rumors were afloat as to weight and value, some stories going as high as 600 pounds, and \$90,000 in value. The truth, however, in this instance, is more startling than rumor. The amount shipped, as the express receipt shows (as exhibited to a friend of ours by one of the lucky parties), is \$189,000, and the weight 820 pounds. Some \$50,000 was shipped at different times, not long since, and about \$26,000 previously, making a grand total taken out, that is known, of some \$265,000, or over a quarter of a million dollars, inside of seven months. The claim is located on Gold hill, in Sonora, at the head of Washington street, a few yards west of the Episcopal church, the tunnel being on a level with the street. Charles Clarke, Joseph Bray and James G. Divoll are the partners, the two former only working in the claim, with no other assistance. This hill has been celebrated for the amount taken out in early days, and has been repeatedly prospected for years since by parties who hoped to find another bonanza. The gulches running from it have also been fabulously rich—especially the run south, crossing the old Condit lot (since mined out with big results) and continuing down through the center of Washington street. Several companies have, at different times, proposed to tunnel down the length of this street, but it was never done, as no arrangement could be made with the city. In '66, Ike Potter, our County Clerk, and two others sank a shaft 40 feet deep and ran a tunnel under Rodgers' house, in hopes to strike the vein. They struck an old tunnel and a big excavation, which looked so shaky that they became disgusted and abandoned the chase. Mr. Dan. Longeway, and others, also worked here for the same object, but failed to find the right spot. It remained for the latter parties, named above, to be more fortunate. These gentlemen have had much experience in quartz mining, and believing they could find a bonanza, started in some months since, and now have a big reward for their faith and well directed labor. They are very reticent about details, and it is difficult to get at all the facts the public would like to know. The quartz yielding the last shipment of \$189,000 was taken out by two of the parties, inside of a week, about two months ago, and they have since been engaged in pounding it out in mortars and running it into bars—the tunnel in the meantime being fastened by an iron gate and heavy lock; no admission given to anyone. The bullion is very fine, and will coin near \$20 per ounce at this Mint. Sheriff Vencey and Assessor Monahan went down with the stage as a guard, and no one outside knew anything about the matter until a day or two after. They were instructed not to stop at Copperopolis, but to go on until they struck the up Milton stage. It was necessary, however, to stop at Copperopolis to brace up the stage, as the immense weight stored in the iron safe under the center seat caused the stage to sag in the middle.

To the Pole in Balloons.

The determination to arrive at the North Pole and solve that mysterious portion of the earth's surface which has heretofore refused to be explored, has now taken the shape of an expedition in balloons, on the plan recommended by Commander Cheyne, R. N. The expedition is to go by ship as far north as possible, and then take flight in aerial means of conveyance from winter quarters during the first week in June.

The average temperature in the early part of June is about 25° Fah. The balloons are named Enterprise, Resolve and Discovery; each will be capable of lifting a ton in weight, the three carrying a sledge party intact, with stores and provisions for 51 days. The ascent will be made on a curve of a roughly ascertained wind circle, a continuation of which curve will carry them to the Pole; but should the said curve deflect, then the required current of air can again be struck by rising to the requisite altitude, as proved by experiments that different currents of air exist according to altitude; this fact Commander Cheyne himself observed when, in charge of the government balloons in his last expedition, he sent up four at the same moment to different altitudes; being differently weighted, they took four different directions to the four quarters of the compass, giving him his first practical idea of ballooning in the Arctic regions. Captain Temple's experiments with the war balloons from Woolwich Arsenal have fully confirmed this important desideratum in aerostation.

About 30 hours would suffice to float our aeronauts from the ship to the Pole, should all go well.

Condensed gas would be taken in steel cylinders, hills would be floated over by expansion and contraction of the balloons, and in the event of any accident occurring, we always have our sledge party, with sledge, boat, stores and provisions for 50 days, intact and ready for service. Scotland has taken up this novelty in Arctic exploration with avidity, and England, though more cautious in the matter, has at last given her adhesion to the project being carried out. Canada is likely to join, and Commander Cheyne has received an invitation from the Canadian Minister of Finance, Sir Samuel Tilly, K. C. B., to deliver his lectures in Canada, with the promise of a warm reception.

MECHANICAL PROGRESS.

The Flexible Shaft.

Although great strides have been made during the past 10 years in all kinds of machinery, the expert recognizes most of them as extensions and developments of known ideas and methods. The principles involved in the flexible shaft are, however, radically different from the principles involved in other machinery. The different stages of its growth towards perfection were so unobserved by the world at large, that when exhibited at the Centennial exhibition, it excited the greatest astonishment of every beholder. Almost all machinery is characterized by fixity in certain planes of motion. The whole value of a turning lathe consists in the maintenance of its centers in a true line, and in all reciprocating machine tools, the moving portions of the mechanism are confined to fixed lines and planes. But here is a device which sets at naught the transmission of rotary motion through straight lines, and conveys it through curves varied at the will of the operator. It upsets all our ideas of rigidity. The first "flexible shaft" was a simple coil of wire, used as a universal joint in sheep-shearing machines, dental and a limited number of light power machines. Flexibility was obtained at a great sacrifice of strength, and the coil therefore made inconveniently large.

Where primitive motion was desirable the angle of torsion was too great, to correct which a coil of wire was wound on a center of flexible material. This was an improvement, but only to the extent of the resistance to compression offered by the filling material. The next step was an important one and consisted in two concentric coils, wound in opposite directions, instead of a single coil. By this arrangement the tendency of the outer coil to contract is met by an equal effort of the inner coil to expand. Flexibility was lost, however, since it required more effort to bend two coils than one. It could not be used on any but light power machines on account of its liability to kink or twist out of line, and double up into twisted loops. The shaft, too, when running at a high rate of speed, vibrated in a very curious manner, dividing into equidistant nodes like the string of a musical instrument, and thus interfering with the proper functions of the working tool, giving it a tremulous motion impossible to control. The defects were finally overcome by enclosing the revolving shaft in a flexible stationary sheath or case, and at the same time the carrying power of the shaft itself was increased by making it solid all the way through, in the sense that wire rope is solid, the sheath enabling an indefinite number of bearings to be given the revolving core, preventing all tendency to kink or vibrate. As now constructed the flexible shaft is made up of a core, a case and appropriate fittings by which the two are joined, rotary motion communicated at one end of the shaft and delivered at the other.

The core is composed of a series of concentric steel wire coils wound hard on each other, the direction of the pitch changing with each layer. The pitch direction of the outside layer is always such that the latter will tend to contract under strain, the shaft always running one way. The case is made of a hollow coil of square wire, with a slight groove on the outer side. This coil is covered with leather, which is prevented from slipping by the groove in the wire. The inside diameter of the case is slightly larger than that of the core, and the ends are furnished with iron ferrules, to receive the driving-pulley and the hand-piece carrying the working tool.

The flexible shaft is not a special tool for a particular purpose, but a connecting link between a given power source and a multitude of tools, and its uses are very varied. It is used in light operations as well as heavier ones, particularly metal drilling. By means of a pair of idler pulleys, mounted one over the other in a weighted frame, and secondly of a pair of pulleys in a swivel frame attached to a hanger adjoining the counter-shaft, the shaft and its drill may be carried at will to any part of the shop.

It reaches into remote corners, and is applied to manifold applications, from drilling, polishing, horse and cattle brushing, morocco finishing, even to hoot blacking. A correspondent of the *London Times*, speaking of this shaft, says: "Pharaoh himself could not have been more surprised at seeing M. ses' rod turn to a serpent than we were to see this rope-like affair eating into the planks set on all sides for it to work upon."

TESTING MACHINES FOR FABRICS.—The custom of testing iron, wood, and other building materials, and testing wire, ropes, cables, etc., and using these tests as a measure of the commercial value of the materials, has proved to be so advantageous that the same idea is being applied to woven fabrics of all kinds. For testing the strength of fabrics, a new machine has been introduced, designed to report pulling strains from half a kilo. up to 250 kilos. The machine consists of an upright standard, supporting a horizontal hollow beam of iron, containing scale levers with a brass weighing scale having a sliding weight and a graduated scale. Suspended from the weighing apparatus is a

clamp lined with leather, and so arranged that when the end of the piece of fabric to be tested is clamped between the jaws the strains will be evenly balanced and distributed. Below this, on the base of the machine, is a roller controlled by a hand-wheel, and round this the other end of the fabric is wrapped, when, on turning the wheel, the strains are applied, and by moving the weight on this scale-beam, so as to keep it continually balanced, a point is reached where the fabric is torn apart. This point shows the breaking strain of the material. The percentage of stretching before breaking may also be found in the same manner. If all fabrics were tested in such a machine, and the breaking point carefully noted and marked on the goods when offered for sale, data would be provided which would place the money value of the goods on an exact basis.—*Scribner for October.*

OSCILLATING AND PORTABLE MELTING FURNACE.—Mr. A. Plat, a prominent founder and machinist in France, has devised an oscillating and portable melting furnace, which is designed to obviate the many inconveniences attending a stationary crucible furnace. The furnace proper is a boiler-iron case, lined with refractory material, and made square so as to save coke; the fuel mostly lodging in the corners and the pot nearly touching the sides. A strong iron band surrounds the case at such a height that it may tip and balance nicely when the pot is about full of metal. By means of the trunnions the furnace is lifted and carried about; levers or carrying bars being employed when carried by men, and a crane used for the larger sizes. In some of the large furnaces, the device is tipped only, and seldom carried out of place, the metal being run into an ordinary ladle. The refractory lining is of best firebrick, or of well-tamped fettling. The furnace is slightly conical below. On the front side is a spout, and at the back a large square opening for the escape of the gases of combustion. The cover is that ordinarily used in foundries. The crucible, which must be fixed therein steadily and permanently, is supported by a "cheese" or flat cylindrical block of refractory material resting on the grate. The spout in front, and a wedge, also of refractory stuff, placed at the back of the pot, hold the whole firm. After the first heat or so these pieces become a unit with the pot. The whole affair rests on two brick supports and receives a blast pipe below if blast is used. The grate is cleaned every two or three heats by slicing from below, tipping the furnace for that purpose. R. Grimshaw, in the *Journal of Franklin Institute*, says this furnace is a great improvement upon the wasteful manner of mounting and using crucibles for melting and pouring steel, brass, etc., which have been in vogue for a hundred years without change. The furnace reduces the consumption of heat to a minimum, and time and fuel in reheating the pot in the coke for the next melting, as well as avoiding all danger of accident from breakage.

BLAST-FURNACE APPARATUS.—In carrying out the improvements of Mr. Thomas Hollis, of Ilkeston, it is proposed to employ a tympan to each open forepart furnace, such tympan with the filling plates and wedges, which secure it in position, is of the width of the open forepart. The central part of the outer side of the tympan projects, and forms a trough over which the cinder passes as it escapes through an orifice in the center of the tympan. In the construction of the tympan and trough there are three or more elongated inlet coils of pipes of a suitable size, the coil nearest the outside of the furnace projects into the body of the trough, and is returned into the tympan, where it is returned upwards, and is connected to three or more return coils of pipe lying over the inlet coils. Round the whole of these pipes the metal forming the tympan and trough is cast, the orifice in the center of the tympan lying between the inlet and outlet coils. By this means he saves considerable time and expense in working the furnace and renewing the fettling, as the tympan and trough is protected from the effects of the heat of the furnace by water circulating through the coils of pipes.—*London Mining Journal.*

IMPROVED ORE STAMP.—J. J. Wait, of Oreana, has invented a new ore stamp, for which he has applied for a patent. The improvements consist of a hollow stamp stem, in combination with a guide rod, making the construction of the stamp cheaper and the stamp less liable to get out of order than those now in use in quartz crushing batteries. The inventor also claims that the stamp can be run with less power than the old stamp, and that any of the stamps in the battery can be taken out and repaired without interfering with the others. The tappets are so constructed that it is impossible for them to slip. The wooden guides, which mill men have long regarded as a nuisance, are dispensed with altogether, and only one bolt has to be removed to take out a stamp stem. A model of a battery with the new stamps is being exhibited there by the inventor. It is a very ingenious piece of mechanism and mill men who have examined it pronounce it far superior to the stamp now in use.—*Nevada Silver State.*

NEW TELEGRAPH APPARATUS.—Prof. Klinkerfues, the director of the Observatory at Göttingen, has patented a new telegraphic invention by which it is said to be possible to send as many as eight messages simultaneously along the same wire. A portion of the invention is an apparatus which simultaneously writes down all the messages as they arrive at the station to which they are addressed.

SCIENTIFIC PROGRESS.

A New Law of Metals.

At the meeting of the American Institute of Mining Engineers held at Montreal last month, Prof. Eggleston read a paper on "A New Law of Metals," which he has discovered by a long continued and important series of experiments on the fatigue of metals.

The so-called fatigue of metals arises from two causes: 1, cold rolling, which produces a cold flow of metals; 2, shocks, either few, heavy and sudden, or many, slight and frequent. The breaks resulting from these causes indicate that the metals undergo not only a physical, but a chemical change. Some of the physical changes have been noted. The fact that a chemical change takes place has not been noticed heretofore. The speaker noticed that blows on metals produced a change in the color of the metals. Certain letters were punched in steel, and, upon etching, they showed white. The same phenomenon was exhibited in metals that had been cold rolled. The fact of fatigue has been frequently noticed, but that it follows laws, and that rupture is both a physical and chemical phenomenon, is new. The question arises, How can these fatigued metals, rendered useless, be restored? There are two ways: first, by rest; second, by heat. This phenomenon, which the speaker called the law of refreshment, is, so far as he knows, a new one. It is constant, and in nearly all metals. The Professor announced that he was constructing a machine with which to study the law. The only exception to this law of fatigue by shock is in the case of tin, which becomes brittle by rest, though tin can be restored by a very low heat. In answer to a question, Prof. Eggleston stated that the chemical change consisted in a change in the condition of the carbon.

The discussion which followed Prof. Eggleston's announcement of this law was interesting. Prof. Silliman gave some instances of the operation of the law of fatigue in the case of grapevine iron and brass wire hung in coils in the laboratory. In answer to a question of Dr. Sterry Hunt, he gave some account of the effect of heat in changing the character of a certain alloy of tin, copper and antimony, which, when first cast, was crystalline and resonant, but lost these characteristics in rolling. The resonance was restored upon heating by plunging into an oil bath of high density. This fact has been largely used in the arts, notably by the Meriden Britannia Company. Dr. Hunt mentioned the well-known fact regarding old Spanish coins that seemed worn entirely smooth, but which were restored so as to bring out the device upon heating. Dr. Raymond suggested that the law was one of alloys, not of metals, and pointed out the similarity of the phenomena described by Prof. Eggleston to those witnessed about a blast furnace in pig iron. Prof. Eggleston replied that, in the sense Dr. Raymond used the word, all metals were alloys. Mr. Holley asked if Prof. Eggleston had examined steel rails that had been cold-straightened as to the gag marks. Prof. Eggleston answered that he had, and that they showed the gag mark every time. Mr. Holley stated that the effect of the use of the gag in cold-straightening on the steel rail was a most important question. At Krupp's works there is a fine of about \$1.25 for the appearance of gag marks on rails. The most prominent engineers in Europe connected with steel works are searching for some method of straightening rails hot that will do away with this effect from the gag.

VEGETABLE IVORY PLANT.—The *Colonies and India* furnish some interesting particulars respecting the so-called "vegetable ivory" which is now so much used as a substitute for ivory. The vegetable ivory used is the produce of a species of palm found wild in South America and Africa. Inside the hard shell is the white kernel, which, being softer than ivory and easily carved, as well as readily dyed, and being less brittle than bone, is largely used in making buttons, etc. The unripe fruit consists of a green shell, containing a watery fluid, which, as the nut ripens, gradually thickens until it becomes a pulpy mass, and eventually hardens into solid matter. The water, though bitter to the taste, is wholesome, and often renders invaluable service to travelers who cannot otherwise obtain water to drink. The tree on which the fruit grows is unlike an ordinary palm, having little or no stem, and drooping downwards, especially when the branches are over-weighted with the six or seven bunches of nuts, each containing six or seven seeds, enclosed in thick, heavy shells and outer sheath, and weighing altogether from 20 to 24 pounds.

INTELLIGENCE OF ANTS.—Sir John Lubbock, in studying the habits and instincts of ants with a view to determine their means of recognizing their fellows, says he took pupae from a nest and divided them, giving part to the nest of a neighbor of the same species and part to the nest of a stranger of the same species. When grown the returned of the pupae from the neighbor were all welcomed. The returned from the stranger were none welcomed, all being attacked and driven. Sir John says that there must be some reason why 100,000 ants in the same nest, who cannot possibly know one another as individuals, are never at war, while should a stranger approach he is at once slain. He concludes that they recognize each other by some smell or other sense quite unknown to us.

The Sensitive Plant Under Anæsthetics.

The idea of subjecting this remarkable plant to the action of anæsthetics was natural, and several experiments of the kind are recorded, the plant having been placed in vapors of ether or chloroform. Recently, M. Arloing has made some interesting observations of the effects of chloral, chloroform and ether presented for absorption by the roots. The pots were sprinkled with aqueous solutions of these substances, then covered with care to prevent escape of the vapors. After absorption of chloroform or ether, one notes primary and secondary effects; the former are phenomena of excitation similar to those arising from mechanical irritation, and comparable to those in animals when anæsthetized. They occur successively from the bottom to the top of the stem. In 30 to 60 minutes the common petioles (or leaf stems) straighten, and the leaflets separate, beginning from the top of the stem; but the plant is now found to have lost its sensibility. The secondary effects consist of elimination of the anæsthetic. The sensibility often does not return for one and one-half or two hours. Chloral does not act anæsthetically on the sensitive plant. These observations afforded M. Arloing an opportunity of ascertaining the velocity of liquids in the stem and branches of plants under strictly physiological conditions, whereas, past experiments on the subject have been made with withered or mutilated plants. If the leaves are in a good state the common petioles bend down suddenly and successively from below upward in the plant as the absorbed chloroform reaches them. Hence, knowing the dimensions of the plant, the velocity of the chloroformized water in the stem and primary petioles can be easily calculated. Within the stem the velocity is modified by the state of the tissues and foliage, the temperature, etc.; it was found in different cases at the rate of 0.90 meters, 2.22m., 2.40m., 2.76m. per hour. The velocity increases from the base to the top of the stem in the ratio of 1 to 1.25 or 1.50, and it is $1\frac{1}{2}$ times to twice as great in the petioles as in the stem. The time of absorption by the roots was found to vary from 2 to $6\frac{1}{2}$ minutes.—*London Times.*

HUMID REDUCTION OF METALS.—An improved mode of operating in the separation of lead, zinc, silver or copper in mixed ores or metallic mixtures has been patented by Mr. F. Maxwell Lyte, of the Scientific Club, Savile-row. The invention relates to the application of a methodical, alternate and continuous system of treatment of ores or metallic compounds by means of acid, wherein by a convenient disposition of the vessels and a special order of decantations the same acid is caused to pass successively over a series of two or more batches of ore, thus becoming completely saturated with the zinc and copper the said ore may contain, and becoming consequently as neutral as possible. Thus while the utmost possible economy of acid is obtained the least possible quantities of lead or iron are carried over in solution with the zinc or copper (the said lead and silver and most of the iron remaining behind with the gangue), so that the lead and silver which have become converted into chlorides can be readily taken up with boiling hme and precipitated together as usual with metallic zinc. He so arranges the attacking vats in which the ore is treated with the acid as to be able to decant the liquids from one of these to any other, and he so ordains the order of the decantations, the withdrawal of the saturated liquors, and the additions of fresh acid, that each time a batch of saturated zinc or zinc and copper chlorides is withdrawn from one end of the series a fresh batch of the acid can be added at the other end.—*London Mining Journal.*

A NEW ALLOY.—An alloy of peculiar beauty and adaptation, as a substitute for silver, is now employed in one of the most celebrated jewelry manufactories in France. It consists of 65 parts of iron, 23 of nickel, 4 of tungsten, 5 of aluminum, and 5 of copper. The iron and tungsten are melted together and then granulated, the water into which the mixture is run for this purpose containing one kilogram of slaked lime and one of carbonate of potash per cubic meter. The nickel, copper and aluminum are also melted together and granulated by running into water containing the same proportions of lime and potash—care being taken during the melting to cover the metals contained in the two crucibles with a flux composed of one part of boric acid to one of nitrate of potash or niter. In the crucible containing the aluminum and copper is placed a lump of sodium of about two grains in weight when treating five kilograms of the three metals—nickel, copper and aluminum—together, to prevent oxidation of the aluminum, and charcoal is also added to prevent oxidation of the copper. The granulated metals are dried, then melted together in the same crucible in the proportions above indicated, and well stirred, after which the alloy is run into ingots. It has the same appearance as pure silver.

MASTODON IN AMADOR COUNTY.—Portions of the fossil remains of a *mastodon giganteus* are frequently plowed up on the ranch of Frank McMurry, in Jackson valley. We have what appears to have been part of a huge tooth. It is a pity that some scientific man does not make a thorough examination of the locality, as the alluvial bottom land of Jackson valley was no doubt the stamping ground of antediluvian animals, compared with which the elephant is only a dwarf.—*Amador Times.*

distance below the surface and form a good ledge. Stoping will be commenced in a short time.

[CONTINUED ON PAGE 236.]

El Dorado County Mines.

Mr. Bennett, in the El Dorado County Republican, writing of the mining interests of that county, says the Pacific has been worked more or less for nearly 30 years, and the aggregate yield \$1,500,000. Owing to litigation and a variety of causes, the mine has lain idle, shafts fallen in and a general state of disuse prevailed, until an enterprising company of Londoners came into possession. Since when, the work has been silently, but steadily going on, in the most satisfactory manner. Two mills, now in process of erection, hoisting works, and restored condition of the shafts and drifts, give promise of speedy and gratifying results, whereby the interests of the entire county will be greatly enhanced and benefited. Its nearness to Placerville, which lies in the shadow of its mills, the abundance of wood, water and other facilities, make it one of the most desirable mining properties on the Pacific slope. The quartz, in color, is an opaque white, finely laminated, carrying free gold and permeated, more or less, with rich sulphuret. The gold is passed by insensible gradation into the rock, and all the indications prove it to be a true fissure vein, causing it to be held in high repute by experts. The dip is toward the east. This lode is in the same great belt as the Keystone mine, in Amador county, and is directly on the "Mother lode." Ore is now being taken out in considerable quantities. The walls are green-stone and black slate. A tunnel tapping the main working shaft at a depth of 160 feet, affords ample ventilation. The Little Elephant, a recent English invention, is being tested. There is claimed for it a capacity of one ton per hour.

The Rose mine is on a lode running parallel with the Pacific, but differing in the character of its quartz. It lacks the green-stone and is very heavily sulphureted. The ore is rich and yields good returns.

In Coon Hollow, above the gold-bearing gravel, is a stratum of volcanic formation, many feet in thickness. The gravel is 15, 20, and even 35 feet in thickness, in many places, and often carries gold throughout its depth. At Reservoir hill the same gravel bed appears. The outer crust is strongly marked, and beneath the volcanic, lies the gravel. Immense results have been realized from these washings at Coon Hollow especially.

Further south the principal mines are still active. Those near Logtown have commanded more or less attention for many years. Rich float has been found in the vicinity, and the red surface dirt, found on all sides, is a favorable indication, while from the earliest days, Mathenas creek was known to be rich. It is a dead river, whose depressions are, to some extent, receiving fresh accumulations every winter by means of "winter streams" that cut through several lodes of auriferous quartz and gravel at its head. The coarseness of gold so deposited proves the nearness of these intersections.

The Springfield or Church Union is thought to be the most valuable lode in this neighborhood. It is handled by San Francisco capitalists. Drifts run north and south from the 500 and 700 levels. The richest ore ever discovered in the mine, has been found on the lowest level, and the sulphureted increase in value with the richness of the ores. The lode at the bottom of the shaft is from four to six feet in width, and is bounded by the country rock, which forms good substantial walls.

A number of lodes, including the El Dorado, Pocahontas, Empire and Excelsior, all in this vicinity, have been worked at intervals, and bear auriferous quartz.

The natural supplies are abundant, and roads not difficult of construction.

PETROLEUM IN PERU.—It appears that F. Prentice, a well-known petroleum capitalist, of Titusville, Penn., is engaged in developing the oil deposits of Peru, having purchased an interest in some 4,000,000 of acres along the Pacific coast. He has contracted to sink 20 wells on the property within the next two years. His prospecting and experiments in that country have demonstrated that it contains the most remarkable oil territory yet discovered. Prentice is introducing crude petroleum for fuel, and people are beginning to use it largely. There are 50 English ocean steamers plying along the coast which contracted with Prentice to use crude petroleum instead of coal as fuel. They are erecting tanks for storing oil at different landings, and pay \$3 a barrel. Sugar refineries are also preparing to use oil in place of coal. He pays a royalty, both to the Mancora estate and the Peruvian government, for the monopoly granted.

PROSPECTING.—The Placer Herald complains of those people who run off to Bodie, Arizona and everywhere under the sun but Placer county to hunt for gold, and say: "It is a cold, unvarnished fact, as the figures will demonstrate, this section of country, right here around Penryn, Newcastle, Ophir and Auburn, is the best district for prospectors in this or any adjoining State. The rock here hardly ever yields less than \$10 or \$12 per ton, often as high as \$40 and \$60, and not unfrequently a regular bonanza is struck. All prospectors, of course, don't strike it big, some hardly ever strike it at all, but the majority do well."

Vein Phenomena of the San Juan.

In a geological talk about the fissure veins of southwestern Colorado, in the San Juan country, H. F. Sickles says, in the Denver Tribune, that silver is the dominant precious metal abounding in the mountains, and is universally found in well-defined fissure veins in the crest of the rocks, where the crevice seems to be filled with an aggregation of mineral matter. In the various forms of metals found in the San Juan mines, may be found the native silver in wire form, in spangles and in grains. It also occurs penetrating crystals, or amorphous fragments of common quartz. The color is dull silver white, often tarnished brown by exterior accretions. It is not often found massive, but most frequently disseminated, and occurs ramose, reticulated and capillary. I have also seen many specimens of ore from our mines containing native silver in the form of crystallized tubes, octahedrons, rhomboidal and in tetrahedrons.

In some of the mineral districts of southwestern Colorado the ores' fruit quite extensively in diorite or antimonial silver, which occurs in grains and in cylinders; also in curved laminae, without cleavage, and fracture uneven.

THE COQUITA PALM TREE.

Another important constituent of our metaliferous deposits is the sulphuret of silver (silver glance). It occurs in octahedrons and in tube form; also reticulated, ramose lamelliform, amorphous and in splottches; cleavage quite imperfect; malleable and sectile, with fracture conchoidal. It is easily distinguished from native silver by its lack of specific gravity and its sulphurous odor under the blow-pipe.

The brittle sulphuret of silver (stephanite) most commonly occurs in hexahedral prisms, but it is sometimes massive and disseminated; structure foliated.

Muriate, or horn silver, is an important factor in formulating the ore in some of our mineral veins, and is a fruitful constituent in the extraction of precious metal.

Sulphureted antimonial silver (pyrargyrite) is found quite abundant in some localities. It is ordinarily membranous in structure and imperfectly foliated, but sometimes occurs in masses and grains; is capillary, and crystallized in hexahedral prisms.

Calcareous matrix is interspersed among nearly all of the ore of San Juan, in the various forms of spar, iron and copper pyrites, as well as the blue scale and fine buckly galena, are found in great abundance.

A RICH strike of ore is said to have been made in the Bingham mine on the Poorman belt, Dakota, showing much free gold and in large pieces.

The Butte Basin.

This basin is now being worked, with a view to full development, by the Butte Basin Gravel mining company. It is situated in Amador county, and is regarded by the Amador Ledger to be of a peculiar formation. Mining experts freely express the opinion that there is nothing like it in the gold-bearing regions of this State, or in any other State, that they are aware of. The basin itself is probably a mile or more in circumference, and is generally conceded to be of volcanic origin. The surface diggings of early days in the basin and all around it, proved remarkably rich—in fact, it was one of the richest spots met with in the State. One of the peculiarities met with hereabouts was that no bedrock was encountered, and when the surface scratching was exhausted miners began to turn their attention to sinking, in the hope that further deposits of gold-bearing gravel would be met with. At various points around the rim of the basin proper rich gravel has been found, some of it yielding as high as \$4 to the pan. One shaft was sunk near the margin to a considerable depth, and gravel, richly impregnated with the coveted metal, was obtained as far as the shaft penetrated into the bowels of the

The Industrial Outlook.

It is cheering to read the papers now-a-days. If one shuns the columns filled with loathsome sensations and horrors, with which nearly all the journals cater to the depraved tastes, from catch-penny motives, he is quite apt to feast upon a stirring industrial article, in which the many little indications of returning life to production and trade are gathered into a panoramic picture of approaching prosperity. This is all the more refreshing because we have been kept so long upon a diet of despondency and disaster. Since 1873 there has been a period of hushed machinery and buttoned pockets. At times signs have appeared of revival, but, though hopefully heralded, they have been followed by but little substance. The industrial disease was evidently one which had laid deep hold upon the material interests of the country, and had to be eradicated by a slow process. The patient had first to outlive the melody, and then recover from its effects. Convalescence has now apparently been reached, and the hearts of the people are cheered by the thought of active-business, profitable production, and a quick turn of the dollar, which will give all a chance to dance to its ring.

Now, what are the indications, or, in other words, the real facts upon which a consciousness of revival is based? One of the leading financial writers of the East enumerates the following points: "The chief source of national prosperity, agriculture, has within recent years attained a very large expansion, and the crops of 1879 will largely exceed all precedent. Having already attained the position of the largest grain-exporting country, we are now beginning, also, to supply animal food in enormous quantities for the markets of Europe, and our dairy products are similarly forcing their way into countries from which they have hitherto been excluded. This development of our vast prairie regions lays the basis for a corresponding increase in the general commerce of the country, and provides employment for the new system of railroads constructed between 1866 and 1873, so largely in excess (as it was then supposed to be) of the prospective requirements of the country, but for which we are now beginning to find very useful employment. Our textile industries are turning out a larger quantity of goods to-day than at any previous period, and, perhaps, at more than an average rate of profit. The iron trade has suddenly recovered its wonted activity, and there is every probability that this year's product of iron and steel will exceed all precedent. The minor industries share equally with the larger ones in the general improvement; and with the exception of coal mining—which is still afflicted with over-production—there is hardly one branch of trade that is not now well and profitably employed. To these facts must be added the further one that, concurrently with very important deficiencies in the grain crops of Europe, we have this year by far the largest crops in the history of the country—a conjuncture which promises to augment our food exports beyond all former experience and to lay the basis for an increase of our inward as well as outward commerce, while it will give extraordinary activity to our transportation interests. These facts more than justify the recovery of confidence that has occurred within the circles of capital during the current year; and that restoration of confidence will give permanence to the renewal of activity that is so generally evident."

The Coquita Palm.

The Coquita palm (*Jubaea spectabilis*) is a Chilean species, but is also cultivated in New Granada and other parts of South America. It affords the *Miel-de-Palmo*, or palm honey, so much esteemed and used throughout that country. The beautiful trees are felled in great numbers yearly, and their graceful crowns of feathery leaves lopped away, to catch the sap running from the wound. By cutting a thin slice from the end every day the flow is kept up for several months. A good tree will yield 90 gallons. The sap is boiled down to the consistency of treacle, and used instead of sugar. The small nuts which the tree bears are also edible, and are exported in considerable quantities. The Chileans let their cows and oxen do the husking in a peculiar manner, as follows: The cattle are very fond of the green husks, and being allowed to feed upon them, swallow the nuts whole. Afterward, when chewing the cud, they eject the nuts, which are found in small heaps, entirely free from husks, in places where the animals have ruminated.

EXTRAORDINARY COAL-MINE EXPLOSION.—It appears, from the report of Professor Burat, that, at the mine explosion at Frameries, more than 100,000 cubic meters of fire damp must have been evolved in a very short time. All the 200 safety-lamps (Mueseler's) were extinguished without causing ignition. The gas issuing from the shaft caught fire outside the mine (possibly from the engine-furnace), and burst with an enormous flame. When the supply was becoming exhausted, the burning gas ran back into the interior of the mine, followed in its retreat by atmospheric air, and occasioned nine consecutive explosions. The whole occurrence is considered unexampled in the annals of coal-mining.—*La Correspondence Scientifique*.

A NEW survey of the Catskills, by Prof. Gayot reveals mountains that were not known to exist. A large part of the region, especially the northwestern, is an untracked forest, and in several places the only chance for making triangulation was by climbing to the tops of high trees.

A 50-FOOT vein of cinabar is reported discovered in Fremont county, showing good prospects at the surface. This is the first quicksilver discovered in Colorado.

THE ENGINEER.

A Balloon Line.

Many plans have been suggested to utilize the lifting power of balloons as a means of carrying passengers over regions inaccessible by any other system of transportation. The latest plan is that proposed in a projected line of balloons run between Spanish Fort and New Lake Eud, in Louisiana, a railway being impracticable on account of the swampy nature of the ground.

The New Orleans *Picayune* says, that while the plan suggested is not original, so far as the principles involved are concerned, the application, however, is ingenious, being, in fact, a successful method of directing the course of the air-ship. Spikes or posts are set along the lake shore, making a complete circuit, resembling a telegraph line. Along on the top of these posts are placed guide rails of a peculiar form. Fitting these rails, and sliding freely on them, are riders or attachments, to which are made fast the guide ropes, holding and guiding the balloon, and so arranged as to brace it against the wind from any direction. Fitted in these posts are pulleys, over which is passed a wire, making a complete circuit like a belt, and gliding on the pulleys; and this rope is moved at any rate of speed by an engine stationed at a proper point in the circuit.

The balloon is made in an elliptical form, the length twice the light, and pointed at the ends, thus giving the least surface for resistance to the atmosphere. From this, suspended by the netting which envelops the balloon, is an iron frame, on which the car is hung by double pivots, similar to a ship's binnacle. The weight being in the car, it remains in its proper position, being braced by the guide ropes, while the float or balloon oscillates above it if moved by the wind.

The car is fitted with a grappling attachment which passes through tackle in the frame and to the car. The moving wire rope is seized by the grappling hook, and the car and float move forward, drawn by the endless rope and guided by the rudders, which slide along the rails, from which it is impossible for them to become detached. If it is necessary to stop, the grapple can be let go instantly and the car stopped. Any number of cars can be used, following each other at short intervals.

The guide ropes can be lengthened at will, and the car allowed to float at any desired height, being under perfect control. The posts having only the weight of the guide rails, and no grading being required, it will be seen that the cost of construction is comparatively small.

This plan appears to be feasible. It remains to be seen how it will work when put in actual operation. If the attempt is successful, the aerial route will be extensively patronized. It is understood that a company is being formed to undertake the enterprise.

TEHUANTEPEC CANAL.—We are informed, by the *Iron Age*, that the work of opening the proposed inter-oceanic route across the Isthmus of Tehuantepec has actually begun. Word has just been received by the syndicate in New York who are engaged in this grand undertaking, that a corps of engineers have commenced dredging, building wharves, surveying, etc., at the mouth of the Goatzacoalcos river, which forms the harbor at the Gulf terminus of the proposed railroad. This enterprise, it will be remembered, is under the authority of a grant or concession recently obtained from the Mexican government by Mr. Edward Larned, of Pittsfield, Mass. No time has been lost in organizing for work and providing the requisite means. By the 15th of October, steel rails, a powerful steam dredge, and every necessary appliance, will be on the ground. About two months will be required to give an entrance for vessels through the bar of 24-feet draft. The grant referred to gives Mr. Larned three years in which to build, the company being bound to construct yearly a section of not less than 63 kilometers, or about 39 miles. The railroad is to start from the mouth of the Goatzacoalcos river and extend to the upper lagoon, near the Pacific ocean, whence a canal must be excavated to the western extremity of the route. The lagoon, or lake, will form a harbor, to be equipped with wharves, lighthouses, etc. The concession from the Mexican government comprises a land grant of alternate sections three miles square, and control of the harbor at the mouth of the Goatzacoalcos for 99 years; also of the lakes on the Pacific side. At the expiration of this period the road must be surrendered to the Government, the latter taking the rolling stock at one-half its appraised valuation and the track at \$13,000 per mile.

COMMANDER CAMERON, of the British navy, says that the Morse system of telegraphy, as far as it depends on the length of sounds, has long been in use in Africa. He has found tribes that, by stationing drummers at intervals, carry intelligence for miles with great rapidity, the beats of the drum being made in accordance with a previous arrangement of signals.

The Italian government is about to construct a large observatory on Mt. Etna. A site has been selected at a height of 9,652 feet above the level of the sea, near the Casa degli Inglesi.

USEFUL INFORMATION.

CHEAP AND SEASONABLE DYES.—Many barks and berries besides the following, enumerated by a German writer, will yield good and beautiful dyes. Many of the fancy inks are little else than fruits, barks or roots, treated similarly to these. The cheap and ready-made aniline dyes of the shops and stores are, however, becoming a common and economical substitute for most of them. The German says: "A number of excellent dyes can be obtained from the berries of common plants, by boiling them in water so as to produce a strong decoction. The whortleberry and the blueberry, when boiled down, with an addition of a little alum and copperas, will make a fine shade of dark blue. The same treatment, with a solution of nut-galls added to it, will make a handsome brown; while, by adding alum, verdigris and sal ammoniac to the berries, several shades of bright purple and red can be obtained. The juice of elderberries boiled in water with a little alum will also produce a shade of blue. The berries of the privet, when over-ripened, will yield, by a mixture of a little salt, a scarlet red, and the seeds of the burning bush, when treated with sal ammoniac, make a beautiful reddish purple. The juice of the currant, with a little alum, will dye a bright shade of red; and the bark of the bush, treated in the same way, makes a good brown. Yellow can be obtained from the bark of the elm, the poplar, the ash and the apple tree, boiled down strong and mixed with alum water. The tassels of broom corn, treated in the same way, produce a good shade of green."

SNOW IMITATIONS FOR PARLOR ORNAMENTS. A neat parlor ornament, inexpensive and readily constructed, can easily be made by the exercise of a little taste and patience, in snow or frost imitations of fern or trees. Take the branch of a tree which is thickly studded with small leaves. They should be painted over with white glue, rather thick; then sprinkle on plaster paris, leaving it much thicker on top. The tree, or rather branch, should be upright while doing this. Put it on pretty thick. You will soon see the damp from the glue go all through the plaster paris. Let it remain until the next day when it will be sufficiently hard for the finish. Now for the secret. Get some clean alum, powder it as fine as possible in a mortar, or otherwise, and sift it through a very fine sieve or piece of coarse muslin cloth. Then get some very clear gum arabic; buy it dry, and sort out the whitest and dissolve it. It must be thick. Brush a good coat all over the plaster paris, after which sprinkle on the powdered alum as quickly as possible. When thoroughly whitened, stand it aside in a dust-proof place, and when dry blow off all the loose alum, and you will be proud of your work.

CELLULAR FORMATION OF IRON.—A writer in the London (*Eng.*) *Journal* asserts that the "fiber" or "silky luster" exhibited in the fracture of good iron, is only the effect of the light reflected from the inner surface of myriads of minute cells exposed by the fracture, the form of which cells in the normal state is spherical, or nearly so, but becomes changed in the process of rolling. That the mechanical properties of tenacity, ductility, etc., must greatly depend on the perfection of this cell system, is argued from the fact that a crystalline, malleable iron does not show prisms in its fracture, but simply a number of faces or planes crossing the cells at right angles, cutting them off short. The process of rolling iron into plates or sheets does not obliterate these cells, but merely modifies them, as they widen out under pressure; the thin partitions become laminated, and on the regularity of this lamination the quality of the plate very much depends. The cell system of copper is more perfect than that of iron, a result of the pouring of the copper into molds; but the cells are afterward altered by the pressure in rolling, etc., but never destroyed.

GLASS SHOE PATTERNS.—The question sometimes arises whether a patent can be obtained for the mere substitution of a special material for another in the manufacture of a well-known article. In reply, we may state that if the Patent Office is satisfied that in consequence of the substitution a new and important result is obtained, a patent will be allowed. A recent case in point is that of an applicant who asked for a patent for making shoe patterns of glass. It was alleged against the applicant that glass patterns had been previously used for cutting out photo print ovals; also that sheet metal shoe patterns were in common use; and that there could be no invention in merely substituting therefor each a well-known substance as sheet glass. But the Commissioner decided that the use of glass shoe patterns was a useful novelty, sufficient to support a patent, because such patterns enabled the cutter to see any defects in the leather and move the pattern to avoid them, which he could not do with the ordinary patterns. So the patent for glass shoe patterns was allowed.

CURVED ARM PULLEYS.—Formerly pulleys were cast with curved arms, with the idea that they would produce less shrinkage strain, as upon cooling they would yield or spring to the pressure, but the art of proportioning and casting pulleys has been so improved that the curved have little or no advantage over the straight arms.

PROTECTION AGAINST REVOLVING SHAFTS, ETC.—Accidents arising from the entanglement of some portion of an operator's garments in a swiftly revolving shaft are of too frequent occurrence in large manufacturing, and of a distressing or fatal nature. Many suggestions have been made from time to time to prevent, or, at least, lessen, the chances of such accidents. One of the simplest methods of rendering these casualties impossible, without introducing the necessity of constructing a railing or fender about the moving piece in dangerous places, is to cover the shaft with a loose sleeve along its entire length. This may be made of sheet tin or zinc, and to be movable if desired. It should be covered within and at the ends with leather, to prevent noise. Arranged in this manner the friction between it and the revolving shaft would be sufficient to cause the sleeve to revolve with the latter; but in the event of any decided resistance being brought to bear on it, as in case of the entanglement of a workman's garment, the sleeve would be brought to rest and permit of extraction without accident. The same idea of loose covers may be applied to cog-wheels or pulleys, and prove an invaluable protection against loss of life or injury to person.

PRICKLY-PEAR FIBERS FOR MATTING, ETC.—During the recent scarcity, the people at Kunjura, in the Punjab, were driven to obtain a livelihood by the preparation of fiber from the prickly pear. The process adopted by them was to first cut off the blades at the stem, to separate each into thin strips with the hand, to tie these strips up into bundles and immerse them in water for ten days or so. This is said to be a most disagreeable task, as the effluvia given off is horrible, and the juice of the plants is so acid that it is difficult to protect the hands and legs from it. The fibers are of a yellowish-white color, as coarse as horse hair; the material is very strong, and makes excellent ropes and matting; but, owing to its coarseness, it is with great difficulty that it can be converted into paper. White ants do not attack matting made of this fiber.

GIVING A NEW EDGE TO RAZORS.—It is sometimes said that dipping a razor in hot water injures its edge, but the contrary is effected. A fine edge is given to steel blades by tempering, and experiment has shown that 212° of heat, or that of boiling water is the point at which razor edges are admirably tempered. Hence, by dipping a razor into boiling water it has the effect of re-tempering it, or giving it a new edge.

GOOD HEALTH.

Poisoned Water.

EDITORS PRESS:—I am glad to see your correspondents waking up to the importance of seeing that their families are not poisoned in their daily drink. But we are beginning at the wrong end. Straining at the gnat and swallowing the camel. By all means see that your pipes and tanks are in good shape, and of right material; but see first that the water supply is uncontaminated. Hardly a town in California is furnished with efficient sewers, and the seepage from the disgraceful, unreformed, old-time cesspool contaminates the contents of probably half the wells in the villages. In Monterey you may find cesspool and well for drinking water in shameless juxtaposition. Still typhoid fever and diphtheria are regarded as mysterious dispositions of Providence, instead of being looked on as the natural result of damnable filthy ways of living, from which the domestic cat recoils. How many farmers have a pestiferous hog-wallow in proximity to their wells, full of stinking black mud, the seepage of which returns back to their tea-kettles? Use dry earth in your privies, and let your hogs wallow a hundred yards from your wells, and give your families a chance for health.—ED. BERNICK, Monterey, Cal.

LONG LIFE, AND HOW TO REACH IT.—This is the title of a new number of the American Health Primers, published by Lindsay & Blackiston, Philadelphia, and for sale in San Francisco by A. L. Bancroft & Co. The unusual excellence of this series deserves a large patronage. The laws of health and causes of disease are set forth in plain language, and in interesting, readable style. Speaking of the universal temptation to forget warnings against danger to health, Dr. Richardson, the author, remarks: "Experience proves that a large majority of mankind has, in every age of the world, preferred to try dangerous coasts and currents for themselves, instead of steering in the well-known track of comparative safety. We are prone to yield to the seductive temptation of finding out for ourselves how great the danger is. We are lured on to venture a trial of strength or endurance by the egotistic opinion that we, of all men, can see the evil consequences, in time to draw back and avoid them." The little book is written with a view of showing common sense facts to common sense people, and void danger to good health.

COLOR BLINDNESS IN NEGROES.—Dr. Swan M. Burnett, of Washington, has recently made some examinations to ascertain whether the negro of the United States is affected with color blindness to the same degree as the white race. He concluded that they are less liable to the defect.

RENEWING THE EYE.—From recent experiments made by M. Philipeaux, a French oculist, it appears that the optic organ has the same capabilities of reconstruction as the bones. M. Philipeaux undertook to discover whether on completely emptying the eyes of young rabbits and guinea-pigs, the vitreous humor would be reorganized and whether even the crystalline would be reproduced. With this view he conducted his operations, always, of course, taking care not to touch the crystalline capsule, for experience has shown that in order for an organ to regenerate, a part of it must be left in its place. It seems that a month after the mutilation was made, M. Philipeaux was able to state that the eyes which had been emptied, were filled afresh, and that the crystalline was reconstituted. He operated on 24 animals, and in every case the mutilated eye revived. How far similar results would be obtainable with the human eye does not appear. If the same regenerating power is found to be general, a decided improvement may be possible in the treatment of certain injuries and diseases of the eye.

RAISINS AS A RECUPERATOR.—It is an old story that of the Frenchman who declined to eat raisins or grapes, because he disliked taking his wine in the form of pills; but now comes Sir William Gull, Queen Victoria's physician, who declares it better, in case of fatigue from overwork, to eat raisins than resort to alcohol. In his testimony before the Lord's Commission in London, a few months ago, he affirmed "that instead of flying to alcohol, as many people do when exhausted, they might very well drink water, or they might very well take food; and they would be very much better without the alcohol." He added, as to the form of food he himself resorts to, "in case of fatigue from overwork, I would say that if I am thus fatigued, my food is very simple; I eat the raisins instead of taking the wine. For 30 years I have had large experience in this practice. I have recommended it to my personal friends. It is a limited experience, but I believe it is very good and true experience."

ANTIDOTE TO POISON IVY.—Dr. J. M. Ward, in the *Medical Record*, makes another addition to the already extensive list of remedies for poisoning by *Rhus radicans*, or "poison ivy." He recommends the profession to use, in all cases of poisoning by this plant, Labarraque's solution of chloride of soda. "The acid poison," he remarks, "requires an alkaline antidote, and this solution meets the indication fully. When the skin is unbroken, it may be used clear three or four times a day; or, in other cases, diluted with from three to six parts of water. After giving this remedy a trial, no one will be disposed to try anything else. It is one of the most valuable external agents known to the profession, and yet seldom appreciated and but rarely employed. It will sustain its reputation as a local application in erysipelas, burns and scalds."

GRAHAM BREAD IN HISTORY.—The *Phrenological Journal* for October is authority for the historical feature of Graham bread. It says: During the administration of Wm. Pitt, in England, there was a great scarcity of wheat, and in order to make it go as far as possible, Parliament passed a law that all the bread for the army should be of unholmed wheat meal. History states that the result was such an improved condition of health among the soldiers as surprised them, and also their officers and the surgeons. The latter declared that never before were the soldiers so robust and healthy; and that disease had nearly disappeared from the army. For a long time this kind of bread was used almost exclusively, but when wheat became once more abundant, its use was discontinued.

A NEW WAY TO TREAT DIPHTHERIA.—Quite a discovery in the treatment of diphtheria has been made here. A young man, whose arm had been amputated, was attacked with diphtheria before healing took place, and instead of the matter incident to that disease being deposited in the throat, the greater portion appeared on the wounded arm, and the diphtheria was very light and easily managed. Dr. Davis, of Mankato, profited by this, and in his next case of diphtheria blistered his patient's chest, and on this blistered part the chief deposits appeared. This was also an easy case of the disease. The theory of Dr. Davis is that diphtheria usually appears in the throat because of the thinner lining of the throat. Hence, when the blister breaks the skin upon any other part of the body, the disease appears there.—*Minnesota Letter.*

TAPE WORMS IN EGGS.—Various instances have been recorded of the discovery in hens' eggs of minute specimens of the *Distoma ovatum*. They appear like a small speck, the size of a millet seed or a pin's head. It is believed by helminthologists that these will develop into one of the varieties of tape worm, and it is wise, therefore, to take eggs hard boiled or otherwise well cooked. A writer in one of the late numbers of *Nature* cites several instances where these parasitic bodies have been found.

A CAUSE OF YELLOW FEVER IN MEMPHIS.—It has been suggested that one of the causes of yellow fever in Memphis is its wood pavements. There are many miles of it in a state of decay—indeed, so rotten and honey-combed as to make them cesspools for the retention of atreptic filth, and where noxious gases are generated that keep the air foul in hot weather by night and by day.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Geology of the San Jose Mining Co.'s Mines, 225. The Week; Public Sentiment Against It; Improved Patent Laws; Scientific Researches, 232. The Colorado River Country; The "Jeannette" in Polar Waters; Cave Dwellers of America, 233. Recent Decisions Relating to Patents, Trademarks, Etc.; Points Under the Mining Laws, Etc., 238. Notices of Recent Patents, 237.
ILLUSTRATIONS.—Geology of Mines in Egan Canyon, Nevada, 225. The Coquita Palm Tree, 230. Cliff Dwellings of the Colorado, 233.
CORRESPONDENCE.—The Mines of Pioneer District, Arizona; Working Gravel Mines at Smartsville; Lake District, Mono County, 226.
MECHANICAL PROGRESS.—The Flexible Shaft; Testing Machines for Fabrics; Oscillating and Portable Melting Furnace; Blast-Furnace Apparatus; Improved Ore Stamp; New Telegraph Apparatus, 227.
SCIENTIFIC PROGRESS.—A New Law of Metals; Vegetable Ivory Plant; Intelligence of Ants; The Sensitive Plant Under Anesthetics; Humid Reduction of Metals; A New Alloy; Mastodon in Amorador Co., 227.
MISCELLANEOUS.—Mining Under-Current on Bear River; Recent Discovery in Tuolumne County; To the Pole in Balloons, 226. El Dorado County Mines; Petroleum in Peru; Prospecting; Vein Phenomena of the San Juan; The Butte Basin; The Industrial Outlook; The Coquita Palm; Extraordinary Coal-Mine Explosion, 230.
MINING STOCK MARKET.—Sales at the San Francisco, California and Pacific Stock Boards; Notices of Assessments, Meetings and Dividends, 228-229.
MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, Oregon and Utah, 228-231.
THE ENGINEER.—A Balloon Line; Tehuantepec Canal, 231.
USEFUL INFORMATION.—Cheap and Seasonable Dyes; Snow Imitations for Parlor Ornaments; Cellular Formation of Iron; Glass Shoes Patterns; Curved Arm Pulleys; Protection Against Revolving Shafts, Etc.; Prickly-Pear Fibers for Matting, Etc.; Giving a New Edge to Razors, 231.
GOOD HEALTH.—Poisoned Water; Long Life, and How to Reach It; Color Blindness in Negroes; Renewing the Eye; Balsams as a Recupercator; Antidotes to Poison Ivy; Graham Bread in History; A New Way to Treat Diphtheria; Taps Worms in Eggs; A Cause of Yellow Fever in Memphis, 231.

Business Announcements.

Averill Mixed Paint, O. S. Orrick, Gen'l Agent, S. F.
Assessment Notice—Alpha Hydraulic Gravel M. Co.

The Week.

Increased activity in prospecting resulting in new developments has been the marked feature of the present week. Judging by reports from the Mohave river, the mountain north of San Bernardino contain rich ledges of silver ore. In Mariposa county, mines that have remained idle for years are now in the hands of parties who propose to work them with a profit. New and promising ledges of free milling gold ore have been discovered in Lassen county. Rich gravel claims, combined with quartz ledges of unusual size and value, are now being worked in Sierra county. One 50-foot ledge of rock of an unknown quality assayed very rich in gold and platinum. In all the region about Milton the indications are extremely favorable for a rich harvest of yellow metal. Within the Glenbrook racecourse enclosure, near Grass Valley, in Nevada county, a quartz ledge has been struck which prospects fairly in gold. The mines of Amorador county are now working to good advantage, some of them having been started up lately after a long period of idleness, and in others new machinery is being put up. All over California, even in unlooked-for localities, energetic and persistent prospecting has reaped just rewards.

Nevada, in relation to the quantity and quality of new discoveries, shows the same evidences of improved mining activity as California. In fact all of the Rocky mountain mining region is fast developing into an active mining business so fruitful as the foundation of solid wealth and prosperity, as speculation has heretofore been a mockery and a hollow delusion.

GOLD has been discovered near Kansas City which runs nine ounces to the ton. A company has taken hold of the discovery and is making arrangements for erecting machinery to work the ore.

Public Sentiment Against It.

While a few of our leading interests are tolerably prosperous and certain branches of business have of late improved somewhat, there is still a great complaint of hard times among the masses in California. Most of our manufacturing and mechanical industries are depressed, labor on nearly every kind is in excess of demand, even at reduced prices, real estate is low, and few improvements are in progress—not that the creation of material wealth has with us been arrested, or even at all restricted. On the contrary, we have made of all our leading staples—gold and silver, wheat, wool, wine, etc.—a large production. But, somehow or another, the proceeds of these commodities have not been generally diffused throughout the community. They seem, indeed, by some mysterious process to have been steadily wrested from the hands of the toiling many, and been aggregated in the hands of the non-producing few.

If now the reader will take it upon him to inquire of the next 10 or 20 intelligent men he may chance to meet what in their estimation are the causes of this untoward and anomalous state of things, we venture the assertion that every one of them, unless biased by interest, will include the practice of dealing in mining stocks among the causes, if, in fact, they do not assign this as the principal one. In other words, it is the sense of all intelligent men whose opinions are judicially entitled to any weight, that this business constitutes one of the most potent factors of the industrial stagnation and financial distress that to-day afflict our people, beside being a source of much crime and an infinite amount of physical suffering and social mischief.

We even go further. We hazard the opinion that there is not a manipulator of the mining share market who will justify the business in which he is engaged on any other than that mankind, being natural gamblers, are bound to indulge this propensity, and may therefore as well stake their money on the turn of the stock market as on the turn of a roulette wheel or the turn of a playing card. It is difficult to find a man, however deeply immersed in the business, who will not readily admit its baneful tendencies, pleading only this universal infirmity of our kind in its defense.

Now the question arises, how long is a business likely to be sustained after it has come to be almost unanimously condemned as demoralizing and dangerous by the community upon which it is dependent for its support. Consulting our reason, we would say not very long; consulting experience, we are prepared to admit that it may, in the absence of restrictive measures, be continued for a great many years. Lotteries flourished for centuries after their pernicious effects were everywhere felt and admitted, it being less than 50 years since the schemes for fleecing the weak and credulous of all classes were suppressed by law, a policy that has met with adoption only in countries where the public judgment is enlightened and the public conscience is especially sensitive. In California, gambling, tolerated from the first, was openly carried on for a good while after it had become utterly obnoxious to the popular feeling, its suppression by statute having been effected less than 20 years ago.

As to the expediency of restraining or entirely prohibiting stock operations by legal enactments, our ablest jurists are not agreed, some arguing in favor of repressive measures, while others incline to the belief that the evil, if let alone, will naturally cure itself, holding, moreover, that nothing short of an unwarranted interference with individual rights would suffice to put a stop to this species of gambling. Evidently, public sentiment would not as yet sustain any very stringent legislation on this subject, and perhaps it is as well to let the thing run in the hope that it will ultimately wear itself out.

Of late the disposition to invest in this class of so-called securities has undergone considerable abatement; but whether this comes from any widespread conviction of the impolicy of the business, or from the little encouragement given dabblers in stocks, it is hard to say. Certain it is that the better class of operators are retiring from the field, which is in danger of being left to the occupancy of the very large and very small, or rather very desperate, class of dealers. Indeed, the calling seems for some time past to have resolved itself into a mere lying-in-wait for the simple and unwary. The utmost ingenuity of the craft has been required to keep their victims from letting go in despair. The most puerile excuses have been invented for explaining the continuance of low prices and postponement of the long-promised "boom" in the market. The last of these was the arrival of General Grant. When he came then prices were to jump up, sales were to take place, and everything be lovely. What is to be thought of a pursuit that has to resort to such means as these to prolong its hold on the popular confidence? Is it not time that all honorable, self-respecting men should withdraw from a business that is even susceptible of deriving aid from a pitiful dodge like this? How in the name of common sense was an event so wholly irrelevant as the advent of any man on this coast to affect the market for mining shares one way or the other?

Improved Patent Laws.

The prominent position assumed by American manufactures and arts, particularly in the domain of the mechanical, during the past decade, has excited much inquiry among foreigners into the workings of a system which has produced such fruitful results. That the success of American inventions is, and their admitted standard of excellence has been due to the stimulus produced by well regulated patent laws, cannot be doubted. There is nothing sluggish in the mind of the American inventor, and the restless activity of his genius aided by comparatively perfect and cheap protective laws, has brought about a condition of things the magnitude of which the European heretofore has not been able to fully comprehend. The English, German and French genius is not naturally sluggish, for we can point to those of that nationality living in the United States who have become so imbued with the spirit of our institutions as to become so to speak "thoroughly American." We cannot, in fact, make any distinction in this country between nationalities. It is the better understood capacities of human nature, and laws calculated to bring out and develop genius which has accomplished a unification of nations as it were, and established a common standard of intellectuality.

On their native soil, however, the condition of things has been and still is adverse to the development and protection of mechanical genius, and in exceptional cases has forced the utilitarian ideas of the people into the domain of the psychological, the mystical. In these departments the palm must be accorded them. A revolution in ideas is, however, occurring in the governing powers of these nations, and learned writers are beginning to see that the practical development of nationality is due more to the advantages accorded material progress, than those which have been heretofore awarded to literature and *belles lettres*.

In England the theory of the patent laws is, to a great extent, founded upon the benefits accruing to the crown upon the exercise of the royal prerogative which grants the monopoly. The expense is heavy, and calculated to destroy rather than nourish the fires of genius that cannot brook control. In France the system has been somewhat broader in extending its benefits to the inventor, still retaining, however, the idea that the Government has bestowed upon the inventor a privilege as distinguished from protection only. In the United States the main idea is that the inventor of any new and useful device is conferring a benefit upon the nation, and should, therefore, be protected in his invention.

This is the correct theory, because it has succeeded in producing such astonishing results that other nations are gradually adopting it. A strong effort is being made to abolish the doctrine that whatever franchises are granted by Government are granted purely voluntarily and by virtue of the exercise of a gracious prerogative. Public policy has been no element in the granting of a patent, and the only other element of any advantage to the inventor, encouragement, wholly disregarded. Royalty has been jealous of parting with its abstract rights as granted it by the *doctrinaires* of an impractical age.

England is seriously contemplating an entire change of front in regard to the policy of her patent laws, induced, no doubt, by the reaction that has set in against the policy she has always adhered to. Under the English system it is not necessary to be an inventor to obtain a patent—the first introducer receives the reward due the discoverer in some other nation. It is, substantially, a reward offered to theft. The idea was, doubtless, good in theory, but disastrous practically, as was discovered not long ago, in the case of the English patent rock-drill, which was introduced in Japan and there found a copyist in an ingenious native, and the English invention was abandoned for the use of the home-made machine. This practical result of their own policy has opened the eyes of English manufacturers to the glaring defects in their patent system, and we may look for a speedy change in the whole, for when once the wedge of improvement has been inserted, ancient customs and ideas must give way to modern utilitarian ideas.

Germany is stirring to improve her patent laws, but they still contain many defects apparent to an American, particularly in the hampering restriction of compulsory working of patents within three years or revocation. Many applications have been refused on the ground that the German law prohibits the grant of a patent a description of which has been published in the *Official Gazette* of the United States—a course which must enure to the hardship of American inventors, but there is no other way than for inventors to shape their course accordingly. The German patent office, not being alone self-sustaining, the fees are high; but it is said that the receipts are now exceeding the expenditures, and a reduction of fees to a reasonable limit will soon be made.

As to the compulsory working of patents, experience in Belgium, France and Austria has shown it to be unjust, and the enforcement of the law in that respect practically abandoned, except in Germany.

Dr. Malapert, Advocate of the French Court of Appeals, in a new commentary on the patent

laws of France, substantially adopts the American idea of protection being due to the inventor, both as an encouragement and as a recompense for the benefit accruing to the public at large after the expiration of the patent; but seems unwilling to declare that the protection accorded the inventor possesses an absolute property in the practical results of his new ideas.

The subject of patents, on account of the great attention paid to it at the present time, will receive a close investigation, and the adoption of a nearly perfect system for the regulation of this peculiar species of property follow.

Scientific Researches.

As the world grows older, the scientific theories promulgated become more numerous. Sometimes a new doctrine is built upon the discovery of some ancient remain, ordinarily termed "pre-historic," because the finder cannot ascertain its origin, or built upon that most deceitful of scientific standpoints, analogy. Some years ago, the supposed remains of a Chinese junk were alleged to have been found near the summit of the Sierras. This furnished food for proof that the waters of the ocean once laved the mountains, for otherwise how could the junk have got there. It also proved that the Chinese had visited this slope long before the present race. There was nothing surprising about either of these deductions, since a critical examination has demonstrated that this coast was at one time submerged beneath the waters of the Pacific, and the annals of the Chinese empire, in the Tong-kien-kang-mon allege that the Chinese visited America in the 4th and 5th centuries. The remains of ancient unknown races and their shell implements are said to be scattered all along the Pacific coast from Alaska to and including Oregon, which latter State seems to have been, however, the favorite habitation for these "pre-historic" races. Only a few weeks ago, a miner discovered, in a hill, on the south fork of Sixes river in Oregon, and in a new and unworked mining region, an old, worn pick, of awkward pattern, and a small coin the size of a dime, composed of gold and copper and of unknown nationality.

The traditional Atlantis is made the basis of the theory of a race of intellectual giants, prosperous and happy, dwelling upon a portion of the American continent, reaching out into the Atlantic ocean, of which Madeira, the Azores and the West India Islands are the sole remnants, all swallowed up in some fearful catastrophe. Central and South America contain fruitful evidences of an unknown, extinct and highly intellectual race, as judged by the ruins remaining. In the canyon of the Colorado, beyond the reach of ordinary warlike tribes, are found the ruins of habitations built by cliff-dwellers, with here and there descendants of the same race, still dwelling in the primitive manner of their ancestors, but possessing few traditions. In the copper region of Lake Superior, hurried beneath what are termed the *debris* of ages, are found evidences of ancient mining. The ancient mound builders, the lake dwellers of Switzerland, and numerous interesting and inexplicable evidences of ancient races are relegated to the dim, misty ages of the past, until our learning in this direction has apparently assumed the shape of legendary lore, and our antiquarians unwittingly fallen into the habits of reasoning peculiar to ancient races.

Whatever is ancient possesses peculiar charms to the mind engaged in antiquarian researches, and exaggerates the capacity that produced the relic into a monument of wisdom or of engineering skill. We can see that all the well concocted theories built upon a bone, a shell, or an old wall, lead to the utter destruction of the theory of evolution, as exemplified particularly in the doctrine of the survival of the fittest, since to discover in the ages of the past superior races, or even equal races, is to assert the deterioration of present races.

Vast changes are occurring upon the surface of the earth even in our day. Mines and mining appliances, well known to exist 30 years ago, are now buried 100 feet beneath the accumulated debris deposited by the hand of man. And shall not nature accomplish by her limitless power far more? What was swallowed up in the cataclysm of 1852 in Tuolumne county, where of what was once a well-peopled region is now a broad lake? What antiquarian of next year will find therein the pick of some modern miner, the shell coin of the Miwok Indians, or the remains of an arastra, and build up fanciful theories of some highly intelligent ancient race? It may be done, and done easily.

Landslides, sudden torrents, and volcanic action of comparatively recent occurrence, but ancient look, cover mountains deep, the remnants, relics and evidences of modern races, habitations and implements, in which the future scientist, now "cramming" in our infant schools, will find food for a splendidly written theme on "pre-historic" remains.

TELEPHONES FOR RAILROADS.—The telephone seems to have become an almost indispensable aid in the operation of railways. The Pittsburg Southern, a narrow-gauge line of 36 miles, is said to have discarded the telegraph and adopted the telephone as a means of communication both for general business and for running trains. The possibilities of this wonderful instrument have only begun to be realized.

The Colorado River Country.

At the meeting of the Academy of Sciences on Monday evening, Major J. W. Powell, of the U. S. Geological Survey, well known as a scientist and explorer, addressed the meeting on the subject of his explorations in the Colorado River country. His highly interesting report on this subject, published a few years since, brought into prominent notice the wonderful features of the region he describes—a region with such marked peculiarities and characteristics as to have attracted the attention of the whole world to its wonders. Although called upon without opportunity for preparation or being provided with notes, Major Powell entertained the Academy for over an hour, with an account of this Colorado region, its geological features, peculiarities, habits of the Pueblo Indians, etc. His manner of speaking is as eloquent as his style of writing is graceful, and the Academy have seldom been entertained as they were by this noted explorer.

The great Colorado river, for nearly 1,000 miles, is not approachable from above. No human industry could thrive; there are no farms, no habitations. The river has carried a vast amount of sediment. The valley of the Colorado is a region of naked rocks, where the strata can be measured with accuracy, where geological studies can be made with an approach to certainty of conclusions. It is an open book, a book of Revelations. We are able now to state with accuracy the amount of material carried off by the river. This amount would average over the whole area a depth, or thickness, of 5,000 feet. A rock as large as the combined States of California and Nevada, and 5,000 feet thick, has been washed away by the storms which have beat upon it, moved it into the river, and the river has carried it away.

Where there has been 1,000 feet of sedimentation, there has been 1,000 feet of degradation in some locality. In the valley of the Colorado, we are able to study the results of the erosion or degradation. These studies have resulted in bringing out interesting facts in dynamical geology. One of these facts is that in this valley the rivers are older than the mountains. The river winds its way over a region of country, carving its channel, cutting its channel deeper and deeper. As the mountains rise, the river cuts its channel through like a saw through a log which is fed to it. Hundreds of instances prove this.

The subject of transportation of material by rivers is a study which is an open book in the Valley of the Colorado. In 1869, I passed through the Grand canyon, and said that the courses of rivers were never determined by factors of strata; but all this is a faulted region. We find the folds in the valley of the Colorado broken by faults. The displacement in these faults is often very great—ten, twelve, fifteen or twenty thousand feet. In the Wasatch mountains, a fault running north and south has been traced 400 miles. In the plateau region, we find simple faults, great blocks, 20 or 30 inches wide, lifted up. There are 11 great faults across the valley of the Colorado. One block dips down, another is lifted up, or vice versa. The structure of the country is displacement by faults. The strata are horizontal. Besides this general structure we find another interesting feature. We find a zone, or belt, of rocks broken into irregular fragments, some blocks tipped one way and some another, on their edges or on their ends, like blocks of ice in a river. We find these zones of broken or irregular rocks, 10, 12, 20, and 30 or 40 miles long. No dynamical theory of a contracting earth explains this structure.

The ride through the Colorado was interesting to us studying geology. When we reached the head of the Grand canyon, our boats were injured. The Grand canyon has its base in granite, and there is generally 1,000 feet of granite rocks, and then carboniferous rocks. We found that the rapids were caused by the granite; that wherever we came to granite the passage was bad. When we came to a fault of sandstone the river would be half a mile or more wide, or at least 200 or 300 yards; but when granite or basalt was reached, it would narrow down to 60 or 70 feet. In this narrow, confined space, as much water as the Ohio river carries will rush and roar down in a mad, wild stream. In the sandstone or shale it opens out broadly. At high water the river fills its channel from wall to wall, and there are no landing places. The difference between high and low water is very great. The river drains an immense region. There are thousands of springs and streams, the waters from which tumble down over the rocks in every direction. In a single great storm, the river will rise twenty, thirty, or even a hundred feet.

At high water the river runs with such irresistible force that oars were of no use, and the boat would sweep along at an alarming and dangerous speed. We found it advisable to travel on the low water, making portages where necessary.

All the falls or rapids are caused by one of two reasons; either the walls have tumbled down and the broken rocks caused them, or else a side channel coming in had washed material into the river bed.

I went down the length of the river in a boat, and there is not a single vertical fall in the whole distance. And here I may mention

certain facts, which I have not before made public, concerning the formation of falls, and which my observation proves to me conclusively. A fall on the river is an exception. A vertical fall needs always an excavation. The Colorado river cuts its own channel, and carves it out so that there can be no fall unless there is some extraordinary circumstance to produce it. It takes two things to produce a fall. One may be a "fault," but here it will not last long—geologically speaking—for the stream will soon wear it away. Or, when a river is somewhat rapid and some strata are hard and some soft. In either case the lower one will be undermined farther than the upper.

Now we know before we started that the Colorado river had to descend 5,000 feet in its course. Geologists said we would assuredly find an immense fall somewhere; or else a series of falls. After exploring the Green and White rivers I concluded that since the Colorado must carry an immense amount of sediment, it would be impossible for it to have many vertical falls. I had faith that there were none. In all the tributaries carrying sediment, there was a very rapid current but no fall. The sediment will wear away the upper strata before the under are undermined, even if the upper are harder.

The Valley of the Colorado has been the home of a Pueblo building people. In the Uintah mountains are thousands of ruins, some of them very ancient and deeply buried. The whole of

nese as knives, having wooden handles. The Utes of Utah, the Shoshonee and Sioux all have these stone knives, which we commonly call their spear-heads. As far as my 20 years' experience among Indians goes, I never saw a stone arrow-head. I have always seen them of bone. What we call spear-heads are really their knives. At Santa Barbara they have opened lots of graves and mounds, and have found numbers of these implements such as we call spear-heads, but many of them have wooden handles yet preserved, these handles being live or six inches long, so that what I have observed has been proved true by these graves. The Indians of Southern California and Utah use a peculiar gum for securing the handles and knives. I found it in graves as far north as Oregon.

The pottery of the Colorado country is very interesting. The most peculiar feature, however, is the picture writing. This art was very highly developed among the Pueblos. The cliffs and rocks are covered in every direction with painted figures, etc. In one wild canyon in northern Arizona, the faces of the sandstone cliffs for 14 miles is almost an unbroken series of pictures. Several of the incidents indicated in this picture-writing I find confirmed in the Buckingham Smith manuscript in the Smithsonian Institution, which is some 300 years old.

When man lives in a primitive condition his

CLIFF DWELLINGS OF THE COLORADO.

the region has been inhabited by people who built houses of two, four, five, six and seven stories in height, and who cultivated the soil to some extent. The Pueblo Indians of to-day are a portion of the same people, allied by their arts only, but with a wide separation in respect to language. There are four distinct stocks of Pueblo language in the United States now.

These people have covered a wide area with their ruins. North, and away west toward the Uintah mountains; east toward the Park mountains of Colorado; about the heads of all the streams piercing the Colorado we find very ancient ruins buried under the drifting sands. As we go down towards the Colorado river, the ruins become more recent. When we come to the deep canyons and high cliffs we find houses three, four and five stories high yet remaining. In the earlier parts of their history they built at the outer part of the valley and heads of the rivers. Here they were probably molested by nomadic tribes, and finally sought safety in the walls of the canyons themselves. The cliff houses do not constitute a distinct style of architecture for the Pueblos, but are much the same style as those built earlier, with a construction and site, however, more specially for defence. The nomadic tribes drove them from the perimeter of the great basin to the river. The Pueblos of to-day are fragments of this ancient people.

The form of axe or hatchet shown here this evening from Tulare lake is one we frequently find. What are here found and called arrow-heads, I have often seen among the Pueblos, in

wants are few. The families live on small pieces of ground and raise corn. There is very little game and no fish, the river being too low down between the cliffs. In this country, where there is only an annual snowfall of four or five inches, they still raise their corn in the drifting sands. They dig a hole twenty inches or two feet deep, and plant the corn in them, the hills being ten or twelve feet apart. They succeed very well. The corn scarcely reaches ten inches above the ground, while it is two or three feet to the bottom of the root. They bake their cornbread very nicely. In a corner of the house is a little oven, with a pottery pipe to lead off the smoke, and a flat hearth on which to bake. The oven is about eighteen inches square. The corn is ground and made into a sort of dough or hatter. The woman takes a handful of this, and spreads it deftly over a stone in a thin film or sheet, like a sheet of paper. This is instantly lifted off and another substituted, until there are seven cooked and laid one upon the other. These seven sheets are then folded into a loaf. They are very particular as to the colors of the corn; that is, in separating the red, blue or white ears; and the head made of these ears is separated also. The chief source of subsistence of these Indians is agriculture, as will be seen from what has been stated.

The Western Union Telegraph Company has made another reduction in its tariff, to take effect Nov. 1st, rates from San Francisco to Eastern cities will be \$2,

The Jeannette in Polar Waters.

It may be safely presumed that by this time the *Jeannette* is fully on her way to her destination, the North Pole. As early as August 27th last, her course was shaped for Cape Serdze Kamen, 67° north, 172° west, to learn particulars concerning Nordenskjöld, who was supposed to be frozen in at Kolintchin bay, news of the coming out of Nordenskjöld not having been received at that date; thence her course was to be directed to Wrangel Land direct. Everything so far has been favorable to the success of this expedition. The *Jeannette* has proved a better sea boat than was anticipated, and the Kuro Siwa flowing in through Behring's straits has assisted her speed. The officers and crew at the date named were in excellent health and spirits. Indeed, the weather has been exceptionally fine and warm, and no ice except the old land ice of last winter clinging to the shore line and every prospect of open water in the Arctic. Up to the 27th August there was no necessity for fur clothing, the temperature even at night not exceeding 35°. The scientific work has not been neglected, and everything that could aid in the gathering of information has been done.

The *Jeannette* has progressed thus far without molestation on the part of Arctic difficulties, and has advanced much further than she could possibly have done at this season of the year had she gone by the eastern route.

This coast has a particular interest in this expedition, inasmuch as San Francisco may be regarded as its home port, and is the first to undertake the attack upon the North Pole through Behring's straits upon the theory of the inflowing Japanese current. It would certainly seem as if success must crown the effort made, because it is so much in accordance with the natural theory that a warm inflowing current like the Kuro Siwa must create an impression upon the ice floes and packs, which on the east are so compact from the never-ending ice-cold polar current flowing out in that direction.

It is hardly to be expected, however, that we shall receive any further communication from the steamer except through entirely accidental sources. From Wrangel Land, which is the last point of civilization in the Arctic, we may receive accounts of her arrival and departure, but that will probably be all. Imagination alone can trace her course towards the settlement of the many questions, shrouded in mystery by the inaccessible region to which all the energies of officers and crew are devoted. Is the north pole the birthplace of storms, or the home of a tremendous volcano? Will Symmes' theory of an opening into the earth be confirmed, or will it all end in the knowledge only of an impenetrable ice barrier? We can do nothing but wait.

Cave Dwellers of America.

The remarkable discoveries that have been made within the past few years connected with the age and origin of the cave or cliff dwellers of America, have been the continual source of much speculation. Southwestern Colorado has seemed to be the location of the most complete discoveries, particularly along the Rio Las Animas and San Juan. The Valley of the Mancos is filled with mounds which appear to demonstrate the existence of numerous villages, from the San Luis valley in Colorado in a continual chain to Mexico. The ruins of these ancient people are found in such various stages of perfection, from the small rock-cut chamber to the massive and imposing structures, indicating the work of different ages, as to afford Senor Altamirano proofs that the Aztecs originated in unsubmerged parts of America, and were as old as the Asiatics themselves, and that Asia may even have been peopled from this country.

Major Powell, however, in another column, sees in these various forms of structure only evidences of the same race building under the different conditions of peace or war. E. T. Elliott discovered and examined in December, 1877, about 12 or 15 of the houses or caves near Del Norte, many of them, especially those along the face of the cliffs, have nearly disappeared from the effects of the disintegration of the rocks. Mr. Elliott says that as no human remains have been found, nor any semblance of graves, it is probable that cremation was practiced.

It is evident from appearance and surrounding that these caves were inhabited during the period when the San Luis valley was an immense lake or sea. The valley is 7,000 feet above the ocean, and the natural inference is that most of the continent at that time was under water, which hypothesis would preclude the idea of their reaching Colorado from Asia.

The Philadelphia papers say there seems no limit to the rise in the iron market there. Manufacturers have a call for all the structural iron they can furnish, and orders cannot be placed except in advance. Plate and tank iron is so largely sold ahead that contracts cannot be made for fear of an advance in the price of material, rates having gone up half a cent per pound during the week.

Business Directory.

ALLEN GOVERNOR.

This Governor is now being generally adopted throughout the United States and Europe. It is without doubt the

Most Perfect Engine Regulator in Use,

And will in most cases save its cost several times a year. It is invaluable on a QUARTZ, FLOUR or SAW MILL ENGINE, or in any Manufacturing Establishment, where Regularity of Speed is desirable. By being able to run the engine to its full capacity, these Governors have in many cases added

Ten Per Cent. to the Productive Capacity of a Mill,

Thus saving more than their cost every week in the month. Every Engine to which this Governor is attached will run with the throttle wide open. The speed of the Engine can be changed by a simple adjustment of the weights. It will give a UNIFORM SPEED WITHOUT REFERENCE TO THE BOILER PRESSURE. It is simple in construction and not liable to get out of order.

Every Governor warranted to give perfect satisfaction. Thirty days given for a trial, and if it does not fulfill all that is promised it can be returned at our expense. In ordering, state the kind of engine, diameter of cylinder, stroke, speed, and average pressure. Send for full descriptive circular.

309 California Street, San Francisco, Cal.
Send for Descriptive Circulars containing testimonials of well-known parties who are at present using them.

Trall Hygienic, Medical and Surgical Sanitarium.

No. 8 Ellis Street, San Francisco, Cal.

Treatment by a Purely Scientific and Rational Method Without Drugs of any Kind.

THE TREATMENT DEPARTMENT EMBRACES ALL APPROVED REMEDIAL AGENTS, AS OXYGEN INHALATIONS, VACUUM TREATMENT, THERMO-ELECTRIC, TURCO-AMERICAN, ELECTRO-MAGNETIC, GALVANO-CHEMICAL, STEAM, VAPOR, WARM AIR, AND ALL FORMS OF WATER BATHS;

Swedish Movements, The Health Lift, Spirometer or Lung Strengtheners, Steam Atomizers, all Electric, Galvanic and Surgical Appliances, Sun Baths, and Solar Ray Surgery, new and perfect Truss for the Radical Cure of Hernia, lately discovered Chemical Compound for the speedy, safe, painless and permanent removal of Cancers, Scientific and successful method for the Cure of Piles, etc., etc.

Aims to keep Abreast with, if not in Advance of the Progressive Age.

It has been the mission of this System to mold public sentiment and this Institution will hope to be no disgrace to the immortal name it has assumed. The time has come when Physicians of this School can afford financially to keep a conscience; in fact it is disastrous financially as well as morally to compromise the truth one iota; hence patients can rest assured that they will be treated by the Physicians after the most approved and scientific methods, out of pure and enlightened selfishness, recognizing the truth and beauty of this great principle: "The Universe is so ordered and arranged that the real and permanent good of every creature is best subserved in promoting the real and permanent good of every other being."

THE BOARDING DEPARTMENT.

The table will be supplied with the best of the excelsior market of the world affords, embracing fruits, grains, vegetables, meats, fish, fowl, eggs, cream, etc. Regular and transient boarders will be accommodated as well as patients. Business and professional men and women who are tired of restaurant fare, may appreciate eating to live a more healthful and enjoyable life. Pure food means pure health. Pure blood means good health.

The vegetarian school has demonstrated beyond the possibility of a doubt that farinaceous dishes, sweet milk and fruit, are sufficient to maintain a hard working man in perfect health. Such a diet might certainly be substituted by sedentary people for their greasy steaks and rigouts. — Popular Science Monthly, December, 1878. The Rooms are pleasant, warm, well ventilated and sunny; convenient to treatment rooms, so as to afford the best advantage of nursing and professional attendance.

GENERAL PRACTICE.

Fever, and in fact all cases may be treated at home successfully. Parturition, confinement cases are taken in the Institution or attended at home in any part of the city or country. Preparatory treatment in these cases is most important. Testimonials of extraordinary cases and cures can be seen on application. The most desperate cases, and especially those that have been given up as incurable by the old methods, are invited. Puerperal and typhoid fever and diphtheria cases, after all other methods have failed, may be said to be a specialty. Send for the TRALL HEALTH JOURNAL.

DRS. D. C. & MRS. E. D. MOORE,

Trall Hygienic Sanitarium, 8 Ellis St. S. F.

Howland's Under-current, Mill and Sluice Riffle.

This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from scouring or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

FRANCIS SMITH & CO.,

Manufacturers of

THE PATENT CHANNEL IRON WHEELBARROWS.

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

SHEET IRON PIPE.

C. C. Bitner's Apparatus for Obtaining Metallic Copper from its Solutions.

Patented March 18th, 1879. Will precipitate with steam in three hours, requiring no machinery to run it. Cost of constructing apparatus, \$75. The old cylinder process takes four hours to precipitate and costs from \$1,200 to \$1,500 to construct, besides the machinery to run it. For right to use my Precipitator address O. O. BITNER, Spenceville, Nevada County, California.

SPECIMENS.

CHOICE SPECIMENS of Quartz showing native Gold, Copper, Galena or Iron Sulphates, Pyrites or Clusters of Crystals, or Petrified Wood sent, postage paid, on receipt of \$1. Address E. O. CRANE, Bodie, Mono County, Cal.

PHOSPHATE SOAP

THE BEST soap for toilet use ever manufactured. BEST because it contains all the excellencies of the most expensive foreign or American soaps without their defects. BEST because it combines strength with delicacy in such a way that its strong detergent qualities do not injure the skin. BEST because it is the result of years of study and experiment in the soap manufacturing business, assisted by modern chemical discoveries. BEST because it contains ingredients beneficial to the skin, which unite chemically with the soap in such a manner as to increase its saponaceous qualities. Every chemist familiar with soap manufacture knows that some ingredients which are in themselves beneficial to the skin cannot be saponified; some are partially neutralized, while others injure the quality of the soap. There are soaps in the market which are to some extent beneficial to the skin, but they are inferior articles for toilet use. PHOSPHATE SOAP is the ONLY article offered to the public which combines all the best elements of toilet soap with medical ingredients beneficial to the skin.

If your wife is in the habit of using cosmetics of any kind, advise her to give up the pernicious practice, as the most harmless face powders obstruct the pores of the skin and sooner or later injure the complexion, while PHOSPHATE SOAP removes all impurities and assists nature in developing a natural, healthy and beautiful skin.

It is an old proverb that an ounce of preventive is better than a pound of cure. Twenty-five cents invested in a cake of PHOSPHATE SOAP will save hundreds of dollars in doctors' bills. It acts as a constant disinfectant, preventing Salt Rheum and other skin diseases.

If your wife will persist in the use of cosmetics, buy her a cake of PHOSPHATE SOAP and tell her to use it every night before retiring. In that way much of the harm will be avoided, as the skin will thereby be able to retain much of its natural vigor and beauty.

No salve or ointment can heal a wound or sore of any kind. Every educated physician will tell you that nature alone can do this. PHOSPHATE SOAP, by its cleansing, soothing and purifying qualities, gives nature a chance to act freely.

Natural beauty surpasses anything which can be imparted by artificial means. PHOSPHATE SOAP gives health to the skin simply by removing impurities and eradicating the poisons which give rise to skin diseases.

Not only for daily use on the face and hands, but for bathing the entire body, there is nothing equal to PHOSPHATE SOAP. It is a thorough disinfectant and removes offensive odors of every kind.

Ladies who have injured the skin by the constant use of cosmetics may do much to restore their faces to that beauty which nature alone can give by constantly using PHOSPHATE SOAP.

For all diseases of the skin use PHOSPHATE SOAP. There is nothing like it for removing impurities and giving the skin a healthy and natural vigor.

Cheap toilet soaps manufactured from rancid and refuse grease injure the skin and are really more expensive than PHOSPHATE SOAP, which retails for 25 cents per cake.

Thousands of articles are palmed off on the public which have no genuine merit, but PHOSPHATE SOAP is the result of modern discoveries of celebrated chemists.

PHOSPHATE SOAP costs no more than other good toilet soaps, while its medicinal qualities make it worth ten times its price to every man, woman and child.

If you want a nice article of Toilet Soap and something that is beneficial to the skin, buy PHOSPHATE SOAP.

Metallurgy and Ores.**Nevada Metallurgical Works,**No. 23 STEVENSON STREET.

Importers of and Dealers in

ASSAYERS' MATERIALS.CHEMICAL APPARATUS AND CHEMICALS, DRUG-
GISTS' GLASSWARE AND SUNDRIES, Etc.

512 & 518 Washington St., San Francisco

We would call the special attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our stock of Clay Crucibles, Mullers, Dry Cups, etc., manufactured by the Patent Plumbago Crucible Co., of London, England, for which we have been made Sole Agents for the Pacific Coast. Circulars with prices will be sent upon application.

Also, to our large and well adapted stock of

Assayers' Materials & Chemical Apparatus,

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.

Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application.

Machinery.**GOLD AND SILVER****Grinding and Amalgamating MACHINERY.**

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

**SPERRY'S Wrought-Iron Frame FOR STAMP MILLS.**

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Builer and Engine, Counter Shafting, Pulleys, etc. Stamps weighing 150 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,250.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold & Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

Will find it to their advantage to call on us at 328 BUSH STREET, bet. Montgomery and Kearny, (up-stairs,) S. F.

[CONTINUED FROM PAGE 229.]

CON. VIRGINIA.—The raise from the 1050 level is passing through porphyry carrying stringers of quartz and is up 15 feet. The drift, 21 ft. thick, running south to connect with the joint B&B Belcher winze from the 1900 level of that mine, is passing through favorable looking rock; total length, 300 ft.

CALIFORNIA.—The raise in the ore vein on the 2150 level is being carried up by 3 sets of timbers in width, the ore being stopped as it proceeds. It is being made to ascertain the extent of the ore of the vein upwards.

MINERAL COX.—The crosscut recently started east on the 2600 level and from a point 125 ft north of the south winze is penetrating quartz giving low assays; total length, 38 ft.

SILVER HILL.—Crosscut on 1300 level is passing through porphyry and low grade quartz, its face 490 ft from its initial point.

EXPOSURE.—The crosscut running west on the 2400 level and 100 ft from the south line is in porphyry carrying some streaks of fine-looking quartz of low grade.

BROPHY.—The south drift in the ledge and from the tunnel level has encountered some ore assaying as high as \$21.30, and is prospecting for more.

EURIEKA DISTRICT.

LEACHING PROCESS.—*Sentinel*: Donald Fraser has been experimenting on a large pile of tailings at Mineral Hill, and says the leaching process proves successful. His brought in 20 pieces "buttons" of silver, extracted from different samples of ore, and varying from one to six ounces in weight and about 800 fin. There are about 50,000 tons of tailings at Mineral Hill that will work \$11 per ton.

ARASTRAE.—The *Lyon County Times* says: "An arastra is being put up in American ravine. This will make the fifth erected in this district during the past 12 months. These small concerns are inexpensive, and invariably yield a good income. A few sites are yet unoccupied, but if they continue to be taken up at the present rate there will soon be none left."

GOOD HOPE DISTRICT.

ELKO COUNTY.—*Reno Gazette*: The district was located about three years ago, but has been neglected until recently. It lies about 70 miles north of Battle Mountain, and three miles west of the Owyhee river. The prospects for development are now pretty bright. Among the most prominent claims there are the Amazon, now bonded to Tuscarora parties for \$20,000; the Page & Kelly, and the Golden Era, bonded for \$10,000 each. The camp needs capital. There is no mill there, and wood is very scarce. F. W. Wetherill has just returned from a six weeks' prospecting trip and says there is a great variety of ore in the district, of which he has brought back numerous samples. There is a very singular formation in the Amazon mine. Against the footwall of porphyry a two-ft vein of a soft talcose substance has been encountered. Before exposure to the air, it is soft, sticky and tenacious like adobe soil; but after drying in the air it solidifies and has the appearance of soapstone, feeling somewhat like talcose slate. Mr. Wetherill proposes to have a specimen of it analyzed.

WILLOW CREEK DISTRICT.

MOONLIGHT MINE.—From the *Silver State* we learn that work is being vigorously pushed forward in the mine. The drift on the ledge at the bottom of the incline is in 90 ft. **GRAB MINE.**—This shows a well-defined ledge, measuring 6½ ft from wall to wall and very rich at the footwall. Ore is being shipped to Salt Lake.

ROCK CREEK.—Rich mines are being worked here. An assay from one owned by Mr. Leonard showed \$170 per ton in silver.

BLUE ATLANTIC. At the head of Rebel creek, is very rich, even the croppings assaying \$140 in silver per ton.

CALL CREEK.—*Idaho Gazette*: Some dams on Fall creek were destroyed by a mudslide with powder and silver rock. The dams formed reservoirs for the water supply of the Blue Tent Gravel mining company. Mr. Courtney of London, the President, and Prof. Thomas Price, the Secretary, came to Emigrant Gap on the train last night to make arrangements for rebuilding the dams destroyed.

ARIZONA.

SANTA CATALINA.—The *Tucson Star* asserts that D. B. Brier is just in from the Santa Catalina mountains, and brings in some fine specimens of rich gold and silver rock from a number of locations in which he is interested. The ores and chlorides and black sulphurets run up as high as \$350 per ton. He reports the facilities for mining and milling of the best, plenty of wood, water and grass, and a climate unexcelled in salubrity and mildness. This is a new district and promises to vie with the other rich mining districts of the county. Mr. Brier sends out supplies to commence developing his claims. We also learn that there are other claims just recently discovered that give high results on assay, going up as high as \$1,300 per ton. It lies about 40 miles from Tucson, and easy of access by the old Fort Grant road.

COLORADO.

BASIN MINE.—*Salt Lake Tribune*: This mine is located at Rosita, about 6 miles from Silver Cliff. Since it was discovered two years ago it has yielded half a million of dollars, with \$140,000 worth of ore now on the dump. The vein is said to be the richest of all the Telluride gold finds. It is now down 240 ft. On every side all the way down is rich ore. A crosscut of 55 ft shows ore all the way, with no indication of waste. The average value of the ore heretofore shipped to the smelters previous to June last was \$226.55 per ton. Selected ores run from \$4,070 to \$7,000 per ton. Telluride boulders worn by water are apparently found in rich earth or clay all through the vein, and grow richer as depth is reached. Pieces of the country rock are found in the vein which look as if they had been boiled in a mineral solution and assay high in gold. The water-worn look of the rich boulders before mentioned, with other indications, are relied upon and seem to sustain the theory that a boiling spring holding minerals in solution was once active in and through the fissure and deposited the rich ores now found therein. The ore is there in sight in large quantities, and experienced mining experts pronounce the ore body enclosed in a fissure vein of great depth and permanency. The mine has been thoroughly timbered, hoisting and pumping works have been added, and the monthly output at from 20 to 25 tons raised per day, is estimated at \$150,000.

WELCH COAL MINE.—The supply of coal from this mine is now producing 240 tons per day, but when cold weather sets in it will be in shape to produce from 300 to 500 tons per day. The mine is situated at Louisville, on the Colorado Central railroad. The vein is from 6 to 8 ft in thickness of solid coal. Workings are 175 ft from the surface, with about 700 ft of drift west, with 15 entries and 21 rooms now being worked. Four miles of track are laid to accommodate the workings which extend north, south and east from the shaft, the immense mass of coal on the east not being broken into yet.

IDAHO.

YANKEE FORK.—An old resident of Nevada just returned says of this new Dorado through the *Silver State*: The mines are rich and extensive, but they have not yet been developed to any great extent. There are no mills in the district, but the country is waiting the completion of the road which is now being built from that place to Bonanza City. There are three arastras in this camp, two of which are used to work ores from the Norton mine. There is one gold claim being worked near Bonanza City, but nothing can be done in the silver mines until mills are built, as the ore does not pay to ship. It is now a poor camp for poor men, and perhaps always will be, as the country will be overrun by Mormons, with whom Nevadans or Californians cannot compete in the labor market. This Custer, one of the prominent mines, has been purchased by a California company with the intention of building a mill and working the mine extensively.

ITEMS.—*Herald*: There are more men at work on Custer mountain at present than at any time since the discovery of the mines. The placer mine of J. G. Morrison,

above the mouth of Jordan, is being worked yet, and yields largely of the yellow dust. A large piece of rock from this Custer, brought down by pack mule last week as a specimen of second-class ore, assayed \$38. The miners and claim owners in Ray, Horse, Kinkikinkie, Ramshorn and Poverty Flat are getting out much high grade ore, and shipments to Salt Lake are going on. J. J. Lamb and James Cassy have discovered a rich vein, 5 ft wide, on the west side of Yankee Fork, and one mile above the saw mill. The ore, as assayed by Shannon & Parks, returned \$40 in gold and \$4 in silver. Some new and rich strikes are reported on the east fork of Salmon. The veins are from 4 to 6 ft in width, and the ore assays \$400 in silver per ton. It is in the best range.

STANLEY BASIN.—A very wide and fine ledge of gold and silver ore was found last week in Stanley basin by Mr. Elliott. The ore assayed here showed \$124 silver and \$52 gold per ton. The ledge is an immense one, being from 20 to 30 ft in width. The ore assayed was from the surface. It has long been believed by miners that Stanley basin possesses some rich quartz mines, as gold is found all over that section, and this discovery verifies their belief. Mr. Elliott was searching for cinabar at the time of the discovery, and is still firm in the belief that he can find the place or ledge from which the rich cinabar float found in the basin comes. Parties have already outfitted and gone to Stanley to prospect for quartz.

OREGON.

STERLING MINE.—*Jacksonville Sentinel*: Work to establish the new base in the Sterling mine is progressing rapidly. A deep cut is being opened just below the point where piping will be commenced. Everything will be in readiness to open on ground of known richness in a short time.

UTAH.

BONHAM GOLD MINE.—The *New York Mail* says: A company is now being organized in this city among prominent capitalists to purchase the well-known Bonham gold mine, situated in Bingham canyon. Prof. Blake, of Yale college, has been selected to examine the mine. The vein is said to be one of the largest yet discovered. It is reported as 100 ft wide, all of which will pay to mill. Enough developments have been made in the Bonham to prove the same a continuous and true ore channel. The claim is now in a condition to produce over 100 tons of ore daily, which, deducting all expenses for mining and milling will net a profit of \$10 per ton.

Recent Decisions Relating to Patents, Trademarks, Etc.

Commissioner's Decisions.

Fastening colors.—*Ex parte* Smith. Decided August 26th, 1879.

1. This question whether a complete process, chemical or mechanical, can be sub-divided—a claim for one of the subdivisions can be joined with a claim for the complete process—turns on the question whether such sub-divisions constitute sub-processes, affecting themselves distinct results subsidiary to the general result of the entire process.

2. An applicant may join in one application a broad or generic claim for a method or process and a specific claim for one of its forms or modifications; but he cannot unite such broad claim with specific claims for two or more of its modifications, nor can he unite in one application two such specific claims without the generic claim.

3. An applicant may join in one application a broad claim for a process of fixing colors, as elements, (1) painting the substance, (2) heating it, (3) subjecting it to the action of vapor, and (4) raising the temperature of the vapor during its application; and a claim for one specific form or modification of the process covered by the broad claim, including, for example, (1) painting the substance with corrosive colors, (2) heating it, (3) subjecting it to the action of vapor, and (4) raising the temperature of the vapor during its application.

4. Two claims, of which one does and the other does not show a gradual increase in the temperature of the vapor as an element of the process of fixing colors, cannot sustain to each other the relation of process and sub-process, nor that of genus and species, and cannot co-exist in one application.

Glass Furnaces.—*Nicholson vs Bennett et al.* Decided August 26th, 1879.

1. Interferences between patents cannot be adjudicated in the Patent Office; but interferences between one or more applications and two or more patents can be adjudicated in the Patent Office, and priority awarded to one of the patents or to an application according to the facts, and such adjudication is binding upon all parties so far as the interference in the Office is concerned, although not conclusive as to the relative rights of the parties outside of the office, nor even in *ex parte* proceedings in the Office.

2. It is the fact, and not the possibility of the claim of an invention by an applicant, which legalizes the declaration of an interference between his application and other applications or patents showing but not claiming the device.

3. Subjects of interference are things, not words; and the same words must mean the same things in their application to several devices in interference.

4. The word "deflecting" is accurately applied to the two inclined planes which constitute the upper walls of the combustion chamber in Arbogast's patent, No. 180,517, dated August 1st, 1876; but it has not the same meaning when so applied which it has when applied to the upper walls of the combustion chamber in Nicholson's application, filed May 28th, 1877, and in Arbogast's patent, No. 188,323, dated March 13th, 1877. On this point, the application and the patent of 1877 are not anticipated by the patent of 1876.

ANOTHER disaster to the Government troops is reported from Colorado—Major Thornburgh's command having been ambushed on Milk river by Ute Indians and suffering heavy loss, the commander of the expedition being among the slain. Active preparations are being made to capture the Indians.

Points Under the Mining Laws, Etc.

There are certain points of orders and decisions by the Interior Department in regard to mineral lands which it would be unnecessary to allude to, because of their being clearly laid down in the law, were it not for the fact that the cases which frequently come before the Interior Department demonstrate that the plainest intendment of the law is the most frequently violated or overlooked. All sorts of points have been decided lately, from those which are fatal to the applicant's claim, down to those which involve the routine of the office.

One of the most important points to be regarded is that in the General Land Office all claims are acted upon in the order of presentation, and there is not the slightest use for any person, no matter how influential he may be, to ask for special privileges. This rule is under a new order of things, and is promulgated by the Commissioner in reply to the daily demand made to have cases taken up out of their proper order.

During the past five months over 500 patents for mineral lands have been issued—a larger number than ever before during the same period of time. This presumes a larger number of applicants, and in the necessary routine of the office, if a claim does not conform in every particular to the rules of the office and of course to the laws, even in the use of ordinary paper fasteners in connecting documents, instead of paste or mucilage, it is not ready to be acted upon, and losing its place goes back to begin over again, perhaps being returned for correction, thus losing considerable time.

Claims are suspended daily in the General Land Office solely because applicants or their agents neglect to conform to the plainest rules of the office. As for instance, they fail to file regulations, to have abstracts of letters certified by the proper officers filed; affidavits as to posting on claim omitted, etc.

Many applications have been "suspended" for want of proof of facts. Lack of proof of citizenship is one of the most common omissions.

Hereafter Registers and Receivers are required to obtain satisfactory non-mineral proof only to date of final proof in all classes of entries, except minerals, upon lands withdrawn or designated as mineral lands. Heretofore the practice has been variable, some officers requiring this non-mineral proof in advance of allowing an entry (other than under the mining laws) of lands withdrawn or designated as mineral.

Discrepancy in description is another and very common reason assigned for suspending a claim after it reaches the General Land Office. In a case lately considered, an adverse claim was rejected because it had been sworn to in San Francisco, when it should have been sworn to in the district where located, the defect being considered fatal.

Another error, also common, is the neglect of the Recorder to attach his certificate and seal to a copy of location notice and affidavit of publication. The sworn facts in any case cannot be made by an attorney, except in the case of a corporation, or one co-owner for another. In all other cases the proof must be made by the claimant. No person who is not in actual possession of land can apply for a patent, and one in possession cannot maintain it except by a hearing to determine the facts, as provided in Sec. 2325 Revised Statutes. An occasion for making this statement arose in the case of the American Flag G. M. Co. vs. The Bennett Lode, Nevada mining district, Gillespie county, Colorado.

Occasionally cases arise in which parties claim repayment from the Land Office, and in a recent case passed upon by the Acting Commissioner of the General Land Office, where money paid in to the local office was misapplied, it was held that the claimant has no claim upon the Government, and that the only remedy was to institute a civil suit for recovery against the Receiver: "Registers of the U. S. Land Offices are not the authorized agents of the Government for the purpose of receiving money from claimants and receipting therefor, and the Government cannot be held responsible for their action in this regard, nor has the Office any authority to allow a claimant credit for money paid to and misappropriated by Registers." A bad state of affairs for the compelled claimant.

Repayments are not made when obstacles to the confirmation of title did not exist through the fault of the Government at the date of sale in cash, or any other disposal of public lands. Appeals from rejection of claims decided by the Commissioner must be made within 30 days.

It is evident that nothing but a little care in complying with all the requirements of the law and rules of the Land Office will enable any claim to avoid a postponement, involving trouble, expense and time. The law evidently takes no note of time, regarding delays, expense, etc., in the light of a well-merited punishment for the non-observance of its tenets.

The Indian Salvador, who murdered Paul Rieger in Marin county, was hanged on the 2d inst. at San Rafael.

JOHN E. GREEN has been awarded \$15,833 for the loss of a leg in the Old Colony railroad disaster in Massachusetts.

PROF. WISE, the aeronaut, ascended in a balloon from St. Louis Sept. 28th, and has not since been heard of.

AN earthquake was felt at Oakland and other places around the bay on this morning of the 2d.

THE United States Assay Office at New York, Oct. 1st, paid out \$639,127 in specie.

THE capital stock of the Bank of California is to be reduced from \$5,000,000 to \$3,000,000.

HON. FRANCIS GILLETTE, ex-United States Senator, died at Hartford, Conn., Sept. 30th.

THE United States steamer *Tuscarora* has been ordered to leave San Francisco for Mazatlan.

THE Treasury purchased 239,000 ounces of silver bullion for the Philadelphia Mint, Oct. 1st.

ACCORDING to dispatches, the insurgents in Cuba are being worsted by the Government troops.

IN a fight between soldiers and desperados in Indian Territory, nine of the latter were killed.

BONDS amounting to \$28,000, stolen from the National bank of Baltimore in 1878, have been recovered.

SMITH, who stole bullion from the S. F. Mint, has been sentenced to four years in the State Prison.

THE industrial parade at Indianapolis was a great success, every branch of trade being represented.

A DETERMINED attempt is being made in Washington Territory to recapture the escaped Perkins murderer—one of them having already been killed by officers.

WATER GAUGE FOR VESSELS.—Jacob Eckhoff, of San Rafael, Marin county, has patented through the MINING AND SCIENTIFIC PRESS Patent Agency an improved water gauge for vessels, by means of which the quantity of water in a ship's hold is indicated at all times. It consists in placing a float valve inside a tube or pipe connecting with the lowest part of the hold; said float being so connected by a cord and gearing as to actuate a pointer on an indicator card or check, as to indicate in feet and inches on the card, the amount of water in the vessel at any time. A check pointer is also connected with the card so that it may be set and the difference in the water level between any one time and another be ascertained, so as to know of any increase or diminution of leakage exactly in inches. The box with the gearing and indicating card may be placed in the cabin of the vessel or elsewhere, and need not necessarily be immediately over the pipe or tube carrying the float, since the cord may be led from the float over suitable pulleys or in supplemental tubes. In this way a very convenient means of measuring the water in a ship's hold is obtained. Ordinarily it is necessary to sound the well by means of a string and weight on a rod; but this is a very unsatisfactory method, and takes some time. With the indicator card always in view the state of the water in the vessel is always known and any increase shown. A bell may be connected with the pointer or gearing so that when over a certain amount of water is in the vessel it will sound the alarm and call the attention of the proper officer to the fact.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.]

FOR THE WEEK ENDING SEPT. 30TH, 1879.
220,076.—WERNICH—Andrew Jackson, S. F.
220,180.—DREDDING MACHINE—S. W. Shaw, S. F.
220,102.—HAND WEAVING TOOL—H. White, Quincy, Cal.
NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

SOLES FOR RUBBER BOOTS.—Charles H. Beach Althaus, Josephine Co., Oregon. No. 219,672. Dated Sept. 16th, 1879. The object of this invention is to provide a leather sole for rubber boots. The method usually adopted is to fasten the leather sole either with screws or tacks directly to the bottom of the boot, which is not always reliable. In this invention the soles are attached in the following manner: The leather main sole is large enough to lap or turn up around the edge of the rubber sole of the boot. To this main sole is fastened a tapsole either with rivets or screws, the tapsole only covering the bottom of the boot, the same as in ordinary tap. The main sole is then fastened to the edge of the rubber sole with small screws or tacks, which are put in horizontally to the rubber sole, thus attaching both soles to the boot. By this method there is no strain or wear on the leather of the main sole or the screws with which said main sole is fastened, so that the bottom of the rubber boot can never leak.

THILL COUPLINGS.—William Quinlan, Mayfield, Santa Clara county, Cal. No. 219,175. Dated Sept. 2d, 1879. The object of the inventor is to produce a means by which the shafts of a vehicle may be readily connected and disconnected without the use of a wrench or other tool, and at the same time have the parts so made that when in position they will not become accidentally displaced. The rear end of the shaft has a bolt passing through it, the outer ends of which are set in hook arms on the clips that secure the axle of a carriage to the bolster. A bail is placed under the shaft-iron and secured by means of the bolt in the shaft; this bail is connected to the clip by a short strap, thus holding the shaft in its place and preventing displacement. The invention is simple and very convenient, and will no doubt meet with ready sale wherever introduced.

WAGON BRAKES.—Harris G. Cox, Alvarado, Alameda Co., Cal. No. 219,692. Dated Sept. 16th, 1879. This invention consists in so constructing the brake that it may be operated by the back-pulling action of the horses, or may be operated by an ordinary band lever, as desired, and may be applied to any ordinary vehicle or street cars. It differs from ordinary horse brakes in that the wagon may be backed at any time without locking the wheels, while at the same time the wheels may be locked if it is desired to do so.

SODA WATER BOTTLES.—B. Hegele, San Jose, Cal. No. 219,723. Dated Sept. 16th, 1879. This device relates to improvements in soda water bottles and stoppers; and the improvements consist in certain details of construction whereby the stopper is made to act in a double capacity, closing the bottle both when it is filled and when it is empty, so that in the latter case all dust and dirt are excluded, and the bottle can only be used for effervescent liquor, which is filled with it when said bottle is in a reversed position.

FASHIONABLE GARDENS are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilions performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

HOW TO STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond this time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Alpha Hydraulic Gravel Mining Company.
Principal place of business, San Francisco, California.
Location of works, Alpha Hill, Nevada Co., California.
Notice is hereby given that at a meeting of the Board of Directors held on the 2nd day of October, 1879, an assessment (No. 1) of Twenty-five cents per share was levied upon the capital stock of said corporation, payable immediately in U. S. gold and silver coin, to the Secretary, at the office of said Company.

Any stock upon which this assessment shall remain unpaid on the Tenth day of November, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the Thirtieth day of December, 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, JAMES IRELAND, Sec'y.
Office, No. 216 Sansome street, San Francisco, California.

Butte Hydraulic Mining Company.—
Location of Principal Place of Business, San Francisco, California. Location of Works, Butte County, Cal.

NOTICE.—There are delinquent upon the following described stock on account of assessment (No. 1) levied on the 20th day of August, 1879, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Am't.
E. Poirson.	13	25	\$25 00
A. G. Hawes.	17	10	100 00
I. M. Scott.	18	10	100 00
W. M. Leland.	19	6	50 00
J. G. Stout.	21	25	25 00
Louis Lapierre.	22	25	25 00
H. Marcoux.	24	25	25 00
John Britt.	20	25	25 00
J. H. Mooney.	27	25	25 00
Zotigue Gervais.	29	5	50 00
Zotigue Gervais.	30	1	10 00
Zotigue Gervais.	31	1	10 00
Geo. W. Deitzler.	37	5	50 00
E. Chaquette.	38	5	50 00
American M. and Dredging Co.	40	5	50 00
N. Desautelle.	41	25	25 00
J. Lucier.	42	25	25 00
N. Goldtree.	43	75	75 00

And in accordance with law and an order of the Board of Directors made on the 23rd day of August, 1879, so many shares of each parcel of such stock as may be necessary will be sold at public auction at the office of the Company, room 20, No. 328 Montgomery street, San Francisco, California, on Tuesday, the 21st day of October, 1879, at the hour of 10 o'clock A. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

L. DENNERY, Secretary.
Office, room 20, No. 328 Montgomery street, San Francisco, California.

Secure Patents and TRADEMARKS.

Through Dewey & Co.'s Scientific Press Patent Agency.

In consequence of spurious imitations of
LEA AND PERRINS' SAUCE,
which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crose and Blackwell, London, &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

Annual Meeting.—Syndicate Mining Co., of Bodio, Mono County, California.

The annual meeting of the above named Company will be held at the office, Room 20, Hayward's Building, 419 California street, San Francisco, Cal., on Thursday, October 16th, 1879, at 1 o'clock P. M., for the purpose of electing a Board of Directors to serve for the ensuing year, and for the transaction of such other business as may properly come before the meeting. Also in accordance with a resolution adopted at a meeting of the Board of Directors, held September 15th, 1879, to take into consideration and decide upon the proposition to increase the capital stock of said Company, from Five Million Dollars divided into fifty thousand shares at the par value of one hundred dollars per share, the present capital of the Company, to Ten Million Dollars, to be divided into one hundred thousand shares of the par value of one hundred dollars each.

THOS. G. TAYLOR,
ROBT. N. GRAVES,
OEO. W. HOPKINS,
CHAS. H. FISH,
Directors.

The transfer books will be closed October 6th, 1879, at 5 P. M.
JACOB STADTFELD, JR., Secretary.

The Pacific Land and Trust Company.—
Location of principal place of business and works, San Francisco and State of California.

Notice is hereby given that at a meeting of the Board of Directors held on the eighteenth day of September, 1879, an assessment (No. 1) of One Dollar and Twenty-five cents per share was levied upon the capital stock of said corporation, payable immediately to the Secretary at the office of the company, 513 California street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on Saturday, October twenty-eighth (28th), 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before will be sold on Saturday, November eighteenth (18th), 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. WM. ANDREWS, JR., Secretary.
Office, 513 California street, San Francisco, Cal.

Dividend Notice.—Office of the Pioneer Mining Company, room 15, No. 310 Pine street, San Francisco, California, September 29th, 1879.

At a meeting of the Board of Directors held this day, a dividend (No. 1) of eight (8) cents per share was declared on the capital stock of the company, payable Monday, October 6th, 1879. Transfer books closed.
J. W. PEW, Secretary.

William Hawkins,

(SUCCESSOR TO HAWKINS & CANTRELL).

MACHINE WORKS,

210 and 212 Beale Street, bet. Howard and Folsom Sts., - - San Francisco.

Manufacturer of

IMPROVED PORTABLE HOISTING ENGINES,

FOR MINING AND OTHER PURPOSES.

Also of the HAWKINS' PATENT ELEVATOR HOIST, for Hotels, Warehouses and Public Buildings.

Steam Engines and all Kinds of Mill and Mining Machinery.

Fulton Iron Works.

Hinckley, Spiers & Hayes.

(ESTABLISHED IN 1855.)

Works, Fremont and Howard Sts. | San Francisco, Cal. | Office, No. 213 Fremont St.

MANUFACTURERS OF

Marine Engines and Boilers,

Propeller Engines either High Pressure or Compound Stern or Side Wheel Engines.

Mining Machinery.

Hoisting Engines and Works, Cages, Ore Buckets, Ore Cars, Pumping Engines and Pumps, Water Buckets, Pump Columns, Air Compressors, Air Receivers, Air Pipes.

Mill Machinery.

Batteries for Dry or Wet Crushing, Amalgamating

Engines and Boilers

of all kinds, either for use on Steamboats and made in accordance with the Act of Congress regulating the same, or for use on land. Water Pipe, Pump or Air Column, Fish Tanks for Salmon Canaries of every description.

Boiler repairs promptly attended to and at very moderate rates.

Pans, Sottlers, Furnaces, Rotorts, Concentrators, Ore Feeders, Rock Breakers, Furnaces for Reducing Ores Water Jackets, Etc.

Sugar Machinery.

Crushing Rolls, Clarifiers, Vacuum Pans, Air Pumps, Concentrators, Bag Filters, Charcoal Filters, Blow-up Tanks, Coolers and Receiving Tanks.

Miscellaneous Machinery.

Flour Mill Machinery, Saw Mill Engines and Boilers, Dredging Machinery, Oil Well Retorts, Powder Mill Machinery, Water Wheels.

Pacific Rolling Mill Co.,

SAN FRANCISCO, CAL.

MANUFACTURERS OF

RAILROAD AND MERCHANT IRON,

ROLLED BEAMS, ANGLE, CHANNEL AND T IRON, BRIDGE AND MACHINE BOLTS, LAG SCREWS, NUTS, WASHERS, ETC., STEAMBOAT SHAFTS, CRANKS, PISTONS, CONNECTING RODS, ETC., ETC.

Car and Locomotive Axles and Frames, and Hammered Iron of Every Description.

HIGHEST PRICE PAID FOR SCRAP IRON.

Orders Solicited and Promptly Executed.

Office, No. 16 FIRST STREET.

PACIFIC IRON WORKS,

First and Fremont Streets, between Mission and Howard, San Francisco, Cal.

RANKIN, BRAYTON & CO.,

Manufacturers of

ENCINES, BOILERS, MARINE AND STATIONARY. PUMPING, HOISTING, AND MINING MACHINERY INCLUDING BATTERIES, AMALGAMATING PANS AND SETTLERS, CONCENTRATORS, ORE FEEDERS, CRUSHING ROLLS AND ROCK BREAKERS. ALSO, WATER JACKET SMELTING FURNACES, FOR REDUCING LEAD, SILVER AND COPPER ORES, QUICKSILVER FURNACES, RETORTS AND CONDENSERS, ROASTING AND CHLORIDIZING FURNACES, SUGAR MILL MACHINERY, WATER WHEELS, ETC., ALL OF THE LATEST AND MOST IMPROVED CONSTRUCTION.

Agents for the Allen Engine Governor, Bailey Air Compressor, Howell's Improved White Furnaces, Walker's Compound Steam Pumps, Etc.

Union Brass Foundry, And Mechanical Workshop.

Manufactures all kinds of Brass Goods, Plumbing, Brewery and Distillery Work, Gas and Soda Apparatus, Mining Goods, Ship Work, Steam Fittings, Water Cates and Valve Meters, Gauges, Counters, Indicators, etc. MACHINE PATTERN and MODEL MAKING a Specialty. Bell and Brass Castings to order at shortest notice. Clock Work Gears cut to order. Highest Market Price paid for Old Metal. For particulars and price lists address

GIOVANNINI & CO.,

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, sheets rolled, punched and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER,

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

Main Street Iron Works,

WM. DEACON, PROPRIETOR.

Noe. 131, 133 & 135 Main St., San Francisco.

Stationary and Marine Engines,

Shafting, Pulleys, and General Machine Work. Jobbing and repairing done promptly and at Lowest Rates. Screw Propellers, Propeller and Steamboat Engines.

SAW MILLS and SAW MILL MACHINERY.

A CARD.

To Parties Interested in Mining and Milling.

Call at J. HENDY'S, N. E. corner of Mission and Fremont Streets, San Francisco, and examine COLEMAN'S PATENT SLUICE. It will save both float and flour. Cold. The best system yet devised. No power required to work it. Examine it and judge for yourselves before purchasing elsewhere.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

GOLD MINE WANTED.

One now paying more than expenses. Address

W. S. KEYES, M. E.,

No. 310 Pine St., Room 42, San Francisco

Good land that will raise a crop every year. Over 14,000 acres for sale in lots to suit. Climate healthy. No droughts, bad floods, nor malaria. Wood and water convenient. U. S. Title, perfect. Send stamp for illustrated circular, to EDWARD FRISBIE, Proprietor of Reading Ranch, Anderson, Shasta County, Cal.

FRASER & CHALMERS
 BOILERS, STAMP MILLS, FUELVANNERS
 (and Machinery) for Systematic Mining, Milling, Smelting and Concentration of Ores.
 No. 145 Fulton St., CHICAGO, ILL.

Winchester Repeating Rifle,

MODEL 1873.

One-third size by Dr. E. H. Tarde.

The Strength of All its Parts,

The Simplicity of its Construction,

The Rapidity of its Fire,

The Power and Accuracy of its Discharge,

The Impossibility of Accident in Loading,

String measuring from center of target to center of each shot, 32 inches. Average distance of each shot, 1 9-100 inches.

Commend it to the attention of all who use a Rifle, either for Hunting, Defense, or Target Shooting.

The San Francisco Agency is now fully supplied with all the various kinds and styles of Arms manufactured by the Winchester Repeating Arms Company, to wit:

Round barrels, plain and set, 24 inch—blue. Octagon barrel, plain, 24 inch—blue. Octagon barrel, set, 24, 26, 28, 30 inch—blue. Octagon barrel, set extra heavy, 24, 26, 28, 30 inch—blue. Octagon barrel, set, 24, 26, 28, 30—extra finished, case hardened and ebeck stocks. Octagon barrel, set extra heavy, 24, 26, 28, 30 inch—extra finished—C. H. & C. S. Octagon barrel, set, 24, 26, 28, 30 inch—beautifully finished—C. H. & C. S., known as "One of One Thousand." Octagon barrel, set, gold, silver and nickel plated and engraved. Carhines blue, also gold, silver and nickel plated. Military rifle muskets, model 1873. Rifles, muskets and carbines, model 1866. RELOADING TOOLS, PRIMERS AND PARTS OF ARMS.

A heavy stock of Cartridges Manufactured by the W. R. A. Co., for all kinds of Rifles and Pistols, constantly on hand and warranted the best in the market.

Sole Agent for Dupont's Mining, Blasting, Cannon, and Celebrated Brands of Sporting Powder.

JOHN SKINKER, No. 115 Pine Street, San Francisco,

SOLE AGENT FOR THE PACIFIC COAST.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding homastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street, - - San Francisco, Cal.

SANDERSON BROS. & CO'S

BEST REFINED CAST-STEEL.

WARRANTED MOST SUPERIOR FOR DRILLS, HAMMERS, ETC.

A full and complete stock of this reliable and well-known brand of Steel, for mining and other uses, now in stock, and for sale at

417 Market Street, S. F., - - H. D. Morris, Agent.

Patented June 25th, 1878.

SAVE YOUR GOLD And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Rifles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO

BULLOCK & CRENSHAW, - 528 Arch St., Philadelphia,

Chemicals and Chemical Apparatus,

Suitable for Analytical, Technical and Experimental Use. Descriptive Priced Catalogues furnished on application

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

Nos. 653 and 655 Mission Street, San Francisco, Cal.

EDWARD G. DENNISTON, - - - PROPRIETOR.

From 1-4 to 10,000 lbs. Weight.

STEEL CASTINGS.
 True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. Gearing of all kinds, Shafts, Dies, Hammerheads, Crossheads for Locomotives, etc. 12,000 Crank Shafts of this Steel now running proved superior to wrought iron. CRANK SHAFTS, CROSSHEADS and GEARING, specialties. Circulars and Price Lists free. Address
Chester Steel Castings Co.
 Works, Chester, Pennsylvania. 407 Library St., Philadelphia

Mining Machinery Depot, PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

A. S. HALLIDIE.

Office, No. 6 California Street, SAN FRANCISCO.

Number 16.

The Field of Chemistry.

Although vast strides have been made in the number of chemical combinations, some of them so remarkable as to border upon the creative act, the field is still limitless. Every new combination, or readjustment of atoms, so to speak, furnishes a foundation for others of still greater perfection. The number of compounds of acids, gases and alcohols reaches into the thousands of millions, so that the student need never fear that there will be nothing left worth investigating. Not every experiment in chemistry is attended with success. Nor does every successful experiment lead to any practical value. It is impossible, however, for any experiment to be fruitless, even if confined to the laboratory, for it adds to the knowledge of properties and to at least a technical value. It is now well known that the majority of fruit essences and flavors are simple chemical combinations, without any element of the natural fruit in them. When petroleum was first discovered in America, or rather when it first came into use, it excited very little attention, except as a liniment for physical ailments, until by a little chemical manipulation it was adopted as an illuminator. The failure of the turpentine product during the war brought into use the lighter product of petroleum, or benzine, in its stead. Further experiments developed lubricating oil, then paraffine, tar, and most wonderful of all, the brilliant aniline colors. In regard to paraffine from petroleum, it may be said that experiments have been in progress to extract the hydrogen atom in its composition and obtain carbon or graphite.

The components of many substances are so well known that they may be compounded as easily as they can be converted into their constituents. Cane sugar may be easily converted into grape sugar (glucose) by the abstraction of the element of water, and why should not grape sugar or glucose be converted into cane sugar? It has probably never yet been accomplished, although synthetic chemistry has many devotees. Kolbe, aware that salicylic acid could be readily converted into carbonic acid, by liberating carbonic acid, reasoned that if he could make carbonic acid act upon and combine with carbonic acid, salicylic acid would be the result. He found a cheap means of accomplishing the synthesis in caustic soda, raising the temperature to give it sufficient energy. Carbon is an element too little understood. It enters into combination with many useful and valuable substances, yet it refuses to be segregated. A diamond can be converted into charcoal, but charcoal has never been converted into a diamond. The paraffine of petroleum consists largely of carbon and an atom of hydrogen, yet nobody has succeeded in liberating that atom of hydrogen. Oxygen, hydrogen, etc., are supposed to be elementary bodies, yet a French chemist demonstrated hydrogen to be a compound, and one of its components so light and of such force as to carry up into the air metallic balls filled with it.

Phenylacetic acid is made from coal tar. This acid furnishes isatine, and isatine may be converted into indigo blue. Bayer reasoned this out from the fact that when indigo is oxidized with nitric acid isatine is formed, and by means of phosphorus and chloride of phosphorus he succeeded in obtaining indigo. Now this conversion of coal tar, etc., into true imitations of nature's own products is a wide and open field, and we may say that we are scarcely beyond the first step towards crossing it.

But it is not this only field unexplored. The charring or converting of one natural product into another is an equally mysterious region scarcely penetrated. The juice of the common carrot may be converted into pectin, the base of all fruit jellies, and flavored with any vegetable jelly prepared by the combination of acids and alcohols, and put upon the market as true fruit jelly of every kind, although perfectly innocent of being evolved from any fruit. Yet it is just the same. Chemical analysis could not demonstrate it to be anything else, so well known already are the elements of natural things. Starch is converted into sugar, and the sugar into alcohol by nature herself. Sawdust is converted into oxalic acid, and old rage into

sweet syrups. Oil of turpentine is isomeric with oil of bergamot, lemon and lavender, but they have never been transposed. There is no reason, however, to suppose that they cannot be. We may say in fact that those things which now seem to be impossible of solution will, by the aid of continual experiment, not only be solved, but will give place to other chemical problems of equal value, which are not now even dreamed of.

THE END OF THE WORLD.—A lecture was lately delivered at the Berlin University, bearing the above ominous title. The learned professor argued that every movement upon our planet, with the exception of ebb and flood tide, which are caused by the attraction of the moon, is occasioned by solar heat. As, however, the sun loses a portion of his caloric every year, science has lately come to the conclusion that as an emitter of warmth, the sun will only last 17,000 years longer. During that space of time our earth will get colder and colder, in proportion as the solar heat shall diminish. The ice will advance from the pole to the equator; the earth's population will gradually recede before the advancing glaciers; the sun will become

New Fly-Wheel Pump.

less and less luminous, until he will present the appearance of a dark red ball; and finally ice will annihilate all vitality on our planet. It is very easy to establish an admitted hypothesis. If solar heat is the source of motion, of course its withdrawal will produce lamentable consequences. Anybody can understand that. But science has not established any such fact. Another scientific writer whose name has escaped our memory, demonstrated with mathematical precision, that the earth's orbit is gradually contracting and the earth approaching nearer the sun in consequence, until finally our planet will become good for solar heat, so far as it goes. Perhaps both theories are partially true. If the sun is losing annually a portion of its heat, so also is the earth annually approaching the sun and in about the same ratio, so that terrestrial conditions must remain unchanged. Climate may have something to do with these theories. A natives of the tropics would probably be convinced that we are approaching nearer the sun, while the Laplander might argue that it was losing its heat. The natives of the temperate zones would be divided in opinion, depending upon an unusually cold winter or hot summer, or vice versa.

The coal burners in Belleville (Ill.) district are preparing for a general strike, to commence on the 15th of this month, unless they are paid three cents per bushel for mining.

Sierra Mojadas Mines.

These mines of Mexico, about the immense richness of which so many glowing accounts have been lately written, are reported as being situated near the Dewey mountain, at a point where Chihuahua, Coahuila and Durango meet, about 200 miles beyond the Rio Grande. These States claim territorial jurisdiction, although a private letter from Matamoros to the Chicago Tribune claims the mines as being undoubtedly in the State of San Luis Potosi. Three States have each a military force in the neighborhood, and suppress all attempts to carry on mining operations. Until within recently, it was supposed that the Mojadas were a part of the public domain, but interested parties made the discovery that the identical tract upon which the richest discoveries have been made was long ago granted away in the usual Mexican style of liberality, to the extent of six Spanish leagues square. It is stated by the writer to the Tribune that not only are the mines private property, but the property of an American. Indeed, the records found in San Luis Potosi, dated November 8th, 1864, declare that Don Manuel Sandoval, of Villanueva, had bargained and sold to Don Jose Adison Da Cue, of Memphis, all his right, title and interest in a certain grant of land from the supreme government. This grant referred to the land upon which the Mojadas mines are located. With the enthusiastic imagination of a correspondent who admits having seen the mine of California, Australia and Ural mountains, the Tribune correspondent says: "Nowhere on this planet have I ever seen the same richness in mines—the same uncounted tons of gold. The very mountains, lofty and rugged as they are, seemed to be built of gold. Untold millions of the yellow ores and dust are in sight; how much there may be hidden

Howland's Undercurrent and Sluice Riffle.

in the heart of the mountains only He who created all wealth can tell.

"If I had not been there, and one had attempted to tell only one-half of the truth in regard to these golden mountains, though he had been my dearest kinsman or most trusted friend, I would not have accepted his story as truth. I shall not ask you to believe me when I say that there are, in those wild, almost inaccessible mountains, great hills of gold, miles in length, hundreds of feet in height, and hundreds of yards in width. And yet it is the literal truth. And not far away from the golden hills there is a mountain of silver ores richer than any ores of Leadville, Virginia, or any bonanza mines yet discovered. This silver mountain throws into the shade the far-famed hill of Santa Eulalia, in Chihuahua, from which \$200,000,000 in silver has been taken. I know you will think I tell incredible stories. I have not told half the truth."

NEW FLY WHEEL PUMP.—We illustrate herewith one of the new pattern fly wheel pumps, made by the Valley Machine Company, of East Hampton, Mass., for which Parke & Lacy, of this city are agents. It is a light bucket plunger pump. Two sizes of this pump are made for a cheap boiler feed or light power, the smallest selling for \$55. The engraving shows its general construction without the necessity of a detailed description.

Inside vs. Outside Amalgamation.

In the ordinary amalgamation of gold on plates, much discussion has arisen as to the advisability of having plates inside the mortar. Where this plan has been adopted there has been saved, at a rough average, about two-thirds the gold on them, the rest of that saved being caught on the apron and other outside plates. As the surface presented for amalgamation outside is usually many times the area of that inside the batteries, those who have practiced inside amalgamation generally believe it to be by far the best. But there are two reasons why inside plates catch so large a proportion, the first of which is simply that they have the first chance at the pulp, which does not reach the other plates until deprived of a large portion of its gold. The other and more important one lies in the motion of the pulp in the battery, which projects it against the plates with some degree of force. Every amalgamator has noticed at some time a color of gold or a small detached fragment of amalgam sliding down a run of plates without being caught until it reached a drop, or by some other means was brought into more forcible contact with the plates than its own weight would insure. This is one of the main points in gold amalgamation too commonly overlooked by our mill men. There are several objections to inside amalgamation. It is customary to have two plates in each battery—one under the feed, the other under the discharges. Both are liable to be marred by hard pieces of ore flying against them, thus rendering them rough and difficult to clean. They cannot be examined at the desire of the operator, and his manipulations must therefore be subject to signs and guesswork, instead of direct observation. The introduction of a plate below the screen necessitates raising the discharge so high as to very seriously diminish the capacity of the mill. Of course this loss depends on the width of the plate; but in some cases it has amounted to as much as one-half the crushing power. Finally, the only advantage gained by inside amalgamation, which, as above stated, is projectile force against the plates, can be readily and much more satisfactorily secured outside, if the situation admits of a little fall.

Taking everything into consideration, it would seem more advisable to confine amalgamation exclusively to outside plates, taking care always to see that they are so arranged as to give several good clear drops in the course of the run. The most satisfactory drop or fall is obtained by running the pulp through a horizontal screen of somewhat larger mesh than that used on the mortar. This separates the stream into a number of smaller ones, and insures contact of every particle in the pulp with the plates beneath, and avoids the loss of drop incurred by a portion of the pulp running back under the projecting lip of the upper plate, and thence merely running down to the next plate, as often occurs in using the ordinary drop.

Howland's Undercurrent Sluice-Riffle.

Among the variety of mechanical appliances utilized in the manipulation of the precious minerals, the mill and sluice-riffle are important. The one in our engraving is deserving of much commendation. It meets a want which has long been felt by gravel miners and millmen, viz: that of a simple, cheap riffle, which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. The arrangement of this riffle is such that there is a strong, unobstructed upcurrent to carry off and break up the gravel or cement, and a slow undercurrent, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from flouing or leakage. There is no mechanical skill required in taking out or replacing the sections.

Messrs. Steiger & Kerr of the Occidental foundry, 137 First street, S. F., have the sole right of manufacturing this riffle.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eps.

Arizona Mining Districts.

EDITORS PRESS:—The distance from the present terminus of the S. P. R. R., at Casa Grande, to Tucson is 75 miles by the stage road, and the time consumed is from 16 to 20 hours. The road is an excellent natural one, but made rough and dusty by the great number of heavy teams passing over it constantly. The first water after leaving Casa Grande is found at Picacho station, 20 miles distant. Water is obtained here from a well 300 feet deep, and is of good quality and abundant. The next is at Desert station, 20 miles from Picacho. Here the well is 200 feet deep, with plenty of good water. From Desert station to Tucson is 27 miles, and water can be obtained at two points on the road. From Tucson to Tombstone district is about 80 miles in a southeast direction, and to Patagonia district about the same distance southwest. The two districts are about 50 miles apart, and show an amazing contrast both in the appearance of the country and the character of the ores. The Tombstone district, now well known as the location of the Tough Nut, Lucky Cuss, Contention and other prominent mines, is being rapidly developed, and as soon as sufficient milling facilities are obtained will assume a prominent place among the bullion-producing districts. The large amount of capital invested within the last three months has given a great impetus to mining and prospecting, and the population is now estimated at 1,500, where four months ago scarcely 100 people were to be found. The veins, as a general rule, are small—one to three feet wide on the surface, and increasing in width as depth is attained. Several large ore bodies have been developed, and the indications are that many of the narrow veins lead into large ore deposits at a depth of 200 or 300 feet. The ores are free milling and generally high grade, \$100 per ton being a moderate estimate for the average. The ore from the Tough Nut and the Lucky Cuss, now being worked at the Tombstone mill, is said to average \$200 per ton, and the yield is \$25,000 per week from a 10-stamp mill. The Contention mine has about \$3,000,000 of ore in sight, and is now building a 20-stamp mill. The owners are said to have refused \$2,500,000 for the mine. A number of the most promising mines have been purchased by Eastern capitalists, and as soon as the railroad is completed to Tucson supplies and machinery will be sent in and the work of development be pushed on rapidly. The great want of the district at present is a custom mill where miners could take their ores to be worked. In sinking shafts on the veins much high-grade ore is extracted, but there being no means of reducing it, it is left on the dumps, where it is soon scattered and carried off. Of 30 tons of high-grade ore taken from the Uncle Sam shaft some months ago, scarcely five tons remain, though no one can see any possible object in carrying it off. This ore was estimated to be worth \$350 per ton; and had the owners any means of working it, they would have realized sufficient to pay for all the labor and expense incurred, and have had a handsome balance left to pay for further developments.

The road from Tucson approaches Patagonia district from the north over a succession of rolling hills and level plains covered with bunch grass and affording excellent grazing for large herds of cattle. As we near the Patagonia mountains the hills become shorter and steeper and are covered with oak timber, scrubby and sparse at first but becoming heavier as we progress until the country assumes the appearance of a vast park, the whole surface being covered with a luxuriant growth of bunchgrass. There are no running streams of water, but springs are found in many places and water may be obtained in the gulches almost anywhere by sinking a few feet, the water being of excellent quality. "Harshaw's Camp" is, as it were, the gate of this mining region, being situated just where the mines begin. It has now two stores, two saloons, a large boarding-house, a lively stable and about thirty houses and tents. Here are the ruins of the old French furnaces, where the ores from the French mines Nos. 1 and 2 were worked years ago, before the country was abandoned to the Apaches, and here the Hermosa company is erecting their furnace. They have come 1,200 tons of ore on the dump, and expect to get their furnace running in about four months. The ores are carbonate and galena, carrying from 20% to 40% lead and from 30 to 120 ounces silver to the ton. They smelt readily without flux and are worked with little expense.

The ore bodies in this district are immense. They seem to have no well defined limits, nor do they run in regular parallel veins, but cross and intersect each other at various angles and in every direction.

The Belmont mine, owned by Page & Bacon, of San Francisco, is located nearly east and west, while the Holland mine and the Wasp run north and south, and the Wasp runs right through the center of the Belmont.

The old Mowry mine is situated about four

miles south of Harshaw's camp; the walls and chimney of the old furnace are still standing. The mine is now the property of E. N. Fish, of Tucson, and has not been worked since Mowry was compelled to leave the country. The ores must have paid enormously to enable Mowry to work them under such tremendous difficulties as he encountered. In the midst of hostile Indians he was compelled to maintain a large force for defense. His nearest base of supplies was 800 or 1,000 miles distant, and much of the distance a desert, destitute of water or feed for stock. It seems almost incredible that he should have obtained machinery and supplies necessary for such an enterprise. It is only within the last six months that Patagonia has become known and attracted any attention. Previous to that time the existence of mines there seems to have been forgotten except by a few persons. Harshaw and his associates were, for a long time, the only persons in the district, and they still retain an interest in their group of mines lately sold to Col. Gillette and others. Eastern capitalists have also purchased some valuable mines and reduction works will soon be erected on an extensive scale.

A number of mines have been bonded for the Eastern market, and in a short time all the promising mines will be in the hands of capitalists who will lose no time in developing them. There is no mining region in the world that presents so many inducements for the investment of capital as this. The ores are rich and work freely, requiring no flux. The ore bodies are large and solid; the workings may be made in solid ore and no waste rock to handle or dispose of. Fuel is abundant and cheap, labor is cheap, bricks for building may be had for \$13 per 1,000 or less.

The railroad will soon pass within 40 miles of the mines, and a good wagon road can be made to the railroad for a few hundred dollars, or freight can be hauled from Tucson for one cent per pound.

Large quantities of ore are exposed on the surface, and wherever shafts have been sunk the ore improves as it goes down.

The Glacier claim has a shaft 50 feet deep, from which the ore was formerly taken by Mexicans, and packed on donkeys five miles to the Santa Cruz river, where it was worked in arastras. The bottom of the shaft still shows rich ore over the whole surface eight feet square.

The Holland mine has a shaft 100 feet deep, and in solid ore all the way. In fact there seems to be no limit to the quantity of ore obtainable, and the time is not far distant when the bullion product of Patagonia district will astonish the world. J. W. W.

Mechanism Shown at Stockton Fair.

EDITORS PRESS:—In proportion to the population there is probably no place on the Pacific coast that has contributed so many useful inventions as Stockton, the city of windmills, the seat of numerous prosperous manufacturing industries. Windmills, plows, harrows, derricks and electric elevators, fanning mills, threshers and harvesters, feeders, self-oiling boxes, composition metals, adjustable car traction, pumps, patent medicines, etc., etc., have been produced here and find favor in a wide market.

While busy with invention, Stockton people are quick to discern and adopt valuable inventions originating elsewhere, and not slow to improve upon them when adopted. Marster's threshing machine feeder is an example. Patent feeders work machines at the very top of their capacity, and this present separator is hardly up to the mark. Mr. Lissenden, proprietor of the Pacific Agricultural Works, tells us of two important inventions tested the past season, one of which is an agitator that catches the straw as it comes from the cylinder and prevents churning; the other is a cleaner at the tail of the separator that saves almost the last kernel of grain. They will be placed on the market another season, and will be comparatively inexpensive.

The Follansbee double propeller pump was shown in Stockton for the first time in 1878, and its power in discharging water found it favor with all who saw it. Its triumph was short, however, for two lean thinkers of the Cassius order conspired and invented the Norton single propeller pump, which overthrew the sovereignty of the Follansbee pump before fairly established. This single propeller pump was shown at the last Mechanics' fair in San Francisco, and won from Superintendent Gilmore the praise of being the most useful and important invention exhibited. It was one of the most meritorious inventions shown at the San Joaquin fair, and elicited many inquiries and frequent tests of its capacity.

Its pumping capacity has been hastily estimated as follows:

4 inch pump.....	500 gallons per minute.
6 " " ".....	1,000 " " "
8 " " ".....	2,500 " " "
10 " " ".....	3,500 " " "
12 " " ".....	4,500 " " "

In actual use it has been found to do much better than this. An eight-inch single propeller pump is in use at the Alameda bath-house to pump water from the bay into two bath-rooms. These rooms together have an area of 143,000 square feet, nearly one acre. In four and a half hours time the pump will fill these rooms one foot in depth, which shows a pumping capacity of over 3,900 gallons per minute. There is a

large 12-inch pump, owned by T. B. Bigelow, on Rough and Ready island. It was tested there (an 8-inch) in competition with the Centennial and the Follanshee pumps, and showed such marked superiority that it was retained in preference to the other two. A four-inch pump can be purchased for about \$150, and be operated by two horses. These pumps will be found of great value in irrigation, pumping from streams over high banks, from mines and from the holds of leaking vessels. A company, with Mr. John Jackson at the head, has been formed in Stockton to manufacture these pumps, and when it commences operations we shall give further notice.

Sub-Irrigation.

One of the most important links in the problem of irrigation is the Abestine sub-irrigation system, invented in 1876 and patented in 1879, by E. M. Hamilton, of Los Angeles. The system consists of pipe laid in trenches, about a foot beneath the surface of the ground, out of the way of the plow. The pipe is laid at various distances apart, according to the crop to be irrigated, and is made of sand, lime, cement and water, and hardens in 24 hours so as to carry water.

The machine for making the pipe, while simple in construction and operation, is difficult to describe. It consists of sheet-iron pipe, of from 3 to 6 inches in diameter, according to the diameter of the cement pipe desired, and 3 feet in length; this is placed horizontally in the trench. Another piece of pipe, 2 feet in height, and standing upright, with a funnel-shaped mouth for receiving the sand and cement mixture, is fitted on the horizontal pipe near the back end, and serves as a feeder. The horizontal pipe is open on the lower side, and on the inside are grooves, one on either side, coming together in a V-shape, with the apex near the mouth. On the back end of this horizontal pipe is an upright lever, three feet in length, fastened on a pivot above, and the lower end attached to a rack-plate moving through the slotted grooves opening and closing the pipe as the lever is moved back and forth. Also attached to the lever is a rod, that moves back and forth with the lever and makes the hole in the sand and cement pipe. With each stroke of the lever the machine is propelled backward from 2 to 5 inches, shaping so much pipe. Three men are employed—one to mix the material, one to feed the machine, and one to operate the machine. As soon as the cement pipe is made, and before hardening, holes are made in the top with a conical piece of wood or iron, and in these holes are inserted cork-shaped pieces of wood with holes burned through lengthwise, through which the water rises to saturate the ground. A 5-inch pipe, about a foot in length, is usually set upright over each hole, to prevent earth and roots from clogging it.

We timed a test of the machine in operation on the grounds, and recorded 11 feet of pipe made in 1½ minutes, or at the rate of 440 feet per hour. In field work, including angles and elbows, and working in a trench, 1,600 feet to 2,000 feet is a day's work. The cost is estimated at about one-half cent per foot, including labor. Mr. Hamilton tells us the usual cost per acre for an orchard is \$15 to \$25, and when once laid down will last indefinitely. The advantages of this system are in the ease and certainty with which the water can be regulated; the saving of from three-quarters to nine-tenths of the water, as used in surface irrigation; the prevention of the baking of the surface, and a chilly, disagreeable night air; and the advantage of a loose, mellow, dry surface, with few weeds. The water supply coming from beneath, induces a downward growth of the roots, out of the way of the plow. Fertilizers may be dissolved in the tank or pond, and carried direct to the roots of the trees. In vineyards, perhaps, poisons may be introduced in the water, and thus reach the phylloxera.

Well Boring.

Messrs. Haas & Manning are boring a deep well in Stockton, on Hunter street, near Main. Mr. Haas is using the steam well-borer, which is working admirably, and has penetrated to a depth of 690 feet, striking a small flow of water at 650 feet. It is calculated that at 750 feet a strong flow will be struck. A reamer is used ahead of the pipe, and steam jacks are used to sink the casing. Two wells 200 feet deep and one 550 feet deep were bored by this well-borer at the Stockton paper mills, getting a good stream. One of these steam well-borers was sent into Santa Clara county, but we never heard that it accomplished anything; and another to Los Angeles county, where it was hindered, and it is claimed to have been finally broken up through jealousy of rival well-borers. Mr. Haas is an excellent professional engineer, cool and prudent, and the machine has never failed to work satisfactorily under his management. We venture to assert that he will strike water with the steam well-borer anywhere between the San Joaquin river and a line drawn from Merced City through Modesto to Linden in San Joaquin county.

H. E. HALLETT.

COPPER IN MAINE.—The *Northwestern Miller* says: A copper belt, some two miles long and from 200 to 400 feet wide, has been discovered about the middle of the southern part of Maine, directly on the coast. Some 20 miles to the northward of the copper belt, silver has been found in flakes, masses and filaments. A shaft has been sunk some hundred feet deep, and it is reported that the ore increases in richness with the depth.

Utilizing Blast-Furnace Slag.

The *London Times* says that slag accumulates in the iron-making districts of Great Britain at the rate of nearly eight millions of tons per annum. Various schemes have been undertaken to utilize this vast quantity of apparently useless material without success, until recently Mr. Charles Wood, of Middlesbrough-on-Tees, after five years of careful study and experiment, has succeeded in effecting the conversion of blast-furnace slag into various forms, and in applying it to several industrial purposes upon a practical and commercial scale. At the time when he started upon his investigations there was no instance of slag being manufactured into a commercial commodity in this country, its only known application being that of road making. Mr. Wood, however, has succeeded in utilizing it for the manufacture of building bricks, concrete, cement, mortar and slag wool.

To prepare it for the various forms it is to assume, the slag is converted into sand and to accomplish which it is run from the blast furnaces into a hollow wheel revolving upon a horizontal axis and fitted with iron buckets inside. A bath of water is maintained inside the wheel at the bottom, and is kept in a state of violent agitation by the revolving action. As the molten slag enters the body of water it is immediately disintegrated and assumes the form of sand, this water taking up the heat from the molten slag and giving it off in the shape of steam. A constant flow of water is maintained into the machine, and the sand is separated from it and elevated to the top of the machine by the bucket plates, which are perforated. Arrived at the upper part of the machine, the slag sand is dropped into a spout, and thence finds its way into wooden wagons, by which it is conveyed to the slag works for manufacturers.

At the works the slag sand is mixed with silicic lime and the mixture thoroughly incorporated in the pug-mill of a brick-making machine. After which it is pressed into bricks at the rate of about 12,000 per day. After about six weeks hardening in the open air the bricks are ready for market. They are very tough and do not split when a nail is driven into them, some of them having withstood a pressure of 20 tons.

In another department the manufacture of artificial stone is carried on, the stone molded into chimney-pieces, window-heads, balustrading, and outside ornamental builders work generally. The stone is composed of two and a half parts of finely pulverized slag, and two and a half parts of ground brick to one part of Portland cement. The mixture is run into molds and set quickly, the articles being ready for the market in four or five days. Besides bricks and stone articles, the slag is used for making mortar, cement and concrete. The mortar is a mixture of slag and common lime, the cement being composed of the same materials with the addition of iron oxides. Slag cement also forms the subject of a recent invention by Mr. Frederick Ransome, which is referred to in another column.

Perhaps the most beautiful, and certainly not the least remarkable, outcome of blast furnace slag is slag-wool, or silicate cotton as it is also called, owing to its resemblance to cotton-wool. The process originated, we believe, with Messrs. Siemens Brothers, on the Continent, and the manufacture has been before attempted in England, but as far as we are aware, has not succeeded. As carried out by Mr. Wood at the Tees Ironworks, a jet of steam is made to strike against the stream of viscous molten slag as it is run off from the blast furnace. This jet scatters the molten slag into a stream of shot, which is projected forwards near the mouth of a large tube, in which a couple of steam jets cause an induced current of air. This tube opens into a receiving chamber, composed chiefly of wire gauze, and measuring about 33 feet long by 15 feet wide, and 12 feet high. As each shot leaves the stream of slag it carries a fine thread or tail with it. The shot, being heavy, falls to the ground, while the fine wholly fiber is sucked through the tube and deposited in the chamber. The appearance of this chamber after a charge has been blown into it is singularly beautiful. Not an inch of floor, sides, or roof but is covered with a thick layer of the downy silicate cotton. This cotton is made into mattresses and also used for covering steam boilers, as well as for other purposes where it is desired to prevent the radiation of heat. For this purpose slag-wool is eminently adapted, as it is a very bad conductor of heat, and is moreover perfectly incombustible.

Another useful purpose for which blast-furnace slag has been successfully utilized is that of glass manufacture. The vitreous character of slag indicates a resemblance to glass in its composition. It does, in fact, contain the principal components of glass, but not in proper proportions, and those in which it is deficient have therefore to be added with others which are not present, for example, sand and alkalis. The glass produced is said to be stronger than ordinary glass, and the color can be varied as required, the natural tint being green. A new method of toughening glass has recently been discovered by Mr. Frederick Siemens, of Dresden, and it is proposed to apply this process to slag glass for the purpose of manufacturing railway sleepers and other articles. Details of Mr. Siemens' process are not at present at hand, but, judged by results, it would appear to differ from that of M. de la Bastie, inasmuch as when the toughened glass is broken it does not fly into minute atoms as does De la Bastie's, but simply fractures, somewhat similar to cast-iron.

MECHANICAL PROGRESS.

Hydrometer Vessel.

A new apparatus for propelling vessels has been recently patented in Germany by Dr. Fleischer, and a vessel called the *Pellworm* has been constructed for the purpose of testing the apparatus. The craft is propelled without engine, paddle wheels or propeller, and it is steered without a rudder. The invention is based on the principle of hydraulic reaction, and it embodies several novel and valuable features, which, according to the reports that have reached us, have rendered the hydrometer a success.

The use of a reactive jet of water as a means of urging a vessel forward is not of itself new, but the means employed by the inventor of the hydrometer to draw the water in and eject it are quite novel.

Two cylinders are connected with the steam boiler by suitable pipes, and the steam supply is controlled by the valve. Each steam cylinder has two suction pipes, and two discharge nozzles connected with cylinders by pressure pipes. The suction pipe is provided with a valve, and the discharge pipe has also a valve. Below the cylinders and between the discharge pipes there is a condenser, having connected with it the air and feed pump. The steam used in the cylinders passes through superheaters which surround the chimneys, and its admission to the cylinders, through the valves, is controlled by a float in each cylinder.

The discharge nozzles are swiveled so that they may turn in any direction, and thus control the course of the vessel by changing the direction of the propelling force.

The great difference between this apparatus and its predecessors is that the steam pressure acts directly upon the surface of the water without the intervention of pistons or intermediate machinery. Friction, complications, expense of repairs, liability to breaking, are in a great measure, if not entirely, avoided, and it is said that the method of applying the power has proved highly economical and satisfactory. The boilers of the *Pellworm* and their appurtenances are precisely like other boilers. The steam is admitted to the upper part of the cylinders through the valves, which are controlled by floats, as before observed. The steam forces the water out through the discharge nozzles with considerable velocity, and the reactive force carries the boat forward. The steam is cut off at the early part of the stroke, and the expansive force completes the work. It may be imagined that considerable loss of power might arise from condensation in the cylinders, but as the water is covered with a film of oil, and a certain amount of oil and hot water clings to the surface of the cylinders and covers the inflowing water, the loss is slight. When the water in the cylinders reaches the prescribed level the exhaust valve communicating with the condenser is opened, and as the vacuum is formed water enters the cylinders through the supply valves, and the operation is repeated.

The *Pellworm* is 75 feet long, 12 feet beam, draws 3½ feet of water, is flat bottomed, and is capable of steaming 6 knots per hour. The apparatus develops 25-horse power, and 40% of power of the steam is realized in the propulsion of the boat.

Electric Drawing Apparatus.

An apparatus has been devised by M. M. Bellet and Hallet d'Arros, of Paris, for obtaining by means of electricity autographic stencils of writings and designs capable of being reproduced by lithography or upon metals by the acid-graving processes. A small Ruhmkorff coil, arranged in the following manner, is employed: A metal plate is united to one of the poles by means of a wire, and the other pole is connected to the core of an ordinary blacklead pencil or suitable point by means of a very fine wire. On the metal plate is fastened by means of gum a thin sheet of paper previously dipped in water containing sea salt. The induction coil is then set in action, and the design it is required to reproduce is drawn on the paper attached to the metal plate with the pencil (or point), by which means the two poles are brought together, and the electric sparks dart continuously from the point of the pencil or point, and produce on the thin paper small holes corresponding with the lines of the design. The metal plate should be placed on some insulating substance. The design or writing thus finished, the metal plate is dipped in water and the paper carefully removed. The stenciling thus obtained, it is easy to transfer it to stone by inking a sheet of paper with transfer ink, and then placing the stencil thereon, and covering it with a sheet of white paper, and pressing it sufficiently for the ink to pass through the holes in the stencil. A proof is thus obtained which can be transferred in the ordinary way. The transfer can also be made on zinc, by which a typographical stereotype may be obtained. In order to obtain an engraving or etching on metal it is necessary to proceed as follows:

A well polished copper plate is covered with a thin layer of varnish. On this varnish a sheet of thin paper or suitable material is pressed, and upon executing the writing or design thereon with the electric pencil or point the electric spark will penetrate the paper and varnish at the same time, and leave the metal bare

at all parts touched by the pencil or point. The plate is then dipped in a nitric acid bath of 20°; the acid will attack the metal where not covered with varnish, and after two or three minutes' immersion an engraved plate is obtained from which a great number of copies can be produced, "exactly similar to etchings obtained by engraving on metal."

LARGE CRANK SHAFTS.—At the late meeting of the Institution of Mechanical Engineers, at Glasgow, a paper was read "On the Forging of Crank Shafts," by Mr. W. L. E. McLean, of the Lancefield Forge. The author gave an interesting account, well illustrated by diagrams, of the methods of forging large crank shafts generally in use, and especially of the building-up system, which had for many years been adopted at the Lancefield Forge, an establishment which, as is well known, has a high reputation for this class of work. In the discussion that followed, Mr. Jamieson believed that at no very distant day the Atlantic steamship service would be such that it would be possible to leave Great Britain early in the week and arrive in New York at the end of the week; but this of course would necessitate the employment of larger vessels and more powerful engines. He had had considerable experience in the building up of large shafts in several pieces, and the firm with which he had lately been connected (Messrs. J. Elder & Co.) had constructed in this way a shaft weighing 56 tons, this being a three-throw shaft and built up of 15 pieces. Within the next 10 years, shafts weighing 100 tons would, he considered, probably be required, and he believed that the proper way to construct such shafts was to build them up, a shaft so built up involving much less loss of time for repairs or renewal, in the event of failure, than would be the case with the old shafts.

ELECTRICITY IN THE APIARY.—A correspondent of the *Deutsche Presse* has adopted electricity as a successful means of overcoming the difficulties in handling bees. Trials on large and small clusters, and even on single insects, answered perfectly; the bees coming in contact with the conducting wires fell stunned and motionless to the ground. They were then sorted and marked, according to the strength of the current applied. The time required for their recovery varying from ten minutes to eight hours, was proportionate to the strength of the shock, but all came out of their trance safe and sound. Encouraged by the result of this experiment, Herr Freiwith resolved to try it on a larger scale, namely, on bees in the hive. To this end he introduced the ends of two conducting wires into a fully occupied honeycomb, and turned on the current for a moment; the bees soon lay on the ground, and it was half an hour before they resumed activity. Herr Freiwith then constructed an apparatus in a small box, six inches each way, which, similar to a cartridge pouch, he wore with a strap round his body. The two wires of the apparatus were, when required to be used, fastened to rods of a suitable length, the wires, of course, always projecting over the ends of the rods. These ends were then applied to the swarm, a knob similar to that employed for a room-telegraph being attached to the apparatus, that the current might be turned on at the proper moment.

NEW CRUSHER.—The Blake Crusher Company, of New Haven, have recently perfected a new machine, called the Challenge Rock Breaker, or Sectional Cushioned Crusher, and in examining its construction we can only wonder how the old machine could have given such universal satisfaction for so many years when there was so much room for improvement. In the new Blake all tealee strains are upon wrought iron or steel, instead of cast iron, as in the old machine. It is sectional, and the weight of the heaviest piece of the largest crusher is only 2,400 pounds. It has double the strength of the old form and at the same time its construction is such that it possesses a high degree of elasticity. The first large machine made by the Crusher Company, was tested by throwing between the jaws a steel sledge, while the machine was running 200 revolutions per minute. This test, which would have broken any form of crusher hitherto made, simply stopped this machine without damaging it. The stroke of the jaws may be maintained at any desired length, whatever wear on the toggles, etc., may have been. It is only two-thirds the weight of the old crusher, thus reducing the cost of freight, and is in addition cheaper in price than its predecessor.—*American Machinist.*

NEW METHOD OF SUPPLYING WATER.—The *American Manufacturer* says an important patent has recently been issued, which promises, it is said, to do for cities and towns what the driven well has done for houses and factories, in revolutionizing their water-supply systems. The patent consists in one or more series of driven-well combinations, a common section pipe, connecting the well tops and ending in a suction pump which, it is claimed, will furnish a liberal supply of water for public use. The working of the pump brings into the wells subterranean water deposits, thus making them a substitute for a reservoir and eradicating local impurities. The invention is founded on several discoveries, resulting from recent experiments at Holyoke, and the advantages claimed are the best possible for fire service, and a continuous and abundant supply of absolutely pure water

at a small cost. The discoveries suggesting the patent were, that continuous pumping purifies objectionable water, and that a simple gang of the driven wells can be made a substitute, and more than an equivalent for a reservoir, avoiding expensive embankments, conduits and land damages, and all risks incidental to inclosed surface waters.

SCIENTIFIC PROGRESS.

New Pencil as a Substitute for Ink.

We do not refer here to the aniline pencils which have been in use for some time, but to a quite different pencil which gives a very black writing, capable of being reproduced by the copying machine, and which does not fade on exposure to light. The mass for these pencils is prepared as follows: 10 pounds of the best logwood are repeatedly boiled in 10 gallons of water, straining each time. The liquid is then evaporated down till it weighs 100 pounds, and is then allowed to boil in a pan of stoneware or enamel. To the boiling liquid nitrate of oxide of chrome is added in small quantities, until the bronze colored precipitate formed at first is redissolved with a deep blue coloration. This solution is then evaporated in the water bath down to a syrup, with which is mixed well kneaded clay in the proportion of one part of clay to three and one-half of extract. A little gum tragacanth is also added to obtain a proper consistence.

It is absolutely necessary to use the salt of chrome in the right proportion. An excess of this salt gives a disagreeable appearance to the writing, while if too little is used the black matter is not sufficiently soluble.

The other salts of chrome cannot be used in this preparation, as they would crystallize, and the writing would scale off as it dried.

The nitrate of oxide of chrome is prepared by precipitating a hot solution of chrome alum with a suitable quantity of carbonate of soda. The precipitate is washed till the filtrate is free from sulphuric acid. The precipitate thus obtained is dissolved in pure nitric acid, so as to leave a little still undissolved. Hence the solution contains no free acid, which would give the ink a dirty red color. Oxalic acid and caustic alkalies do not attack the writing. Dilute nitric acid reddens, but does not obliterate the characters.—*Moniteur Scientifique.*

BOOKS OF OLDEN TIME.—From the opening of the ninth century, parchment took the place of papyrus. Ancient books were rolled instead of being in square form, as we have them. About this time paper made from cotton and linen rags began to be made, but its manufacture was so limited that the facility for copying was not much increased. All writing material was exceedingly scarce in that age, and had the invention of printing dated earlier, it could not have made any substantial progress on this account. In many instances the only way to issue a new work was to erase the original writing from a manuscript, and then to trace another book upon the same parchment. Thus the writings on many valuable manuscripts were destroyed, and some even more valuable than those which took their place. Written language had almost perished for the want of material upon which to record the burning thoughts which were struggling for expression. The books of those days were written out by hand, and the work of the copyists was both honorable and lucrative. They were generally employed by booksellers on a salary. The rich employed favorite slaves to copy works of antiquity and of their own times, for their own libraries. Orators secured the copying of their own discussions; and the government, of its edicts.

DISCOVERY IN PHOTOGRAPHY.—The Cincinnati *Commercial* says that Judge Longworth, after months of experiment, has discovered the process used by a few old-world photographers in the preparation of sensitized or dry glass plates. The value of this happy result cannot be overestimated. By the method referred to the amateur or landscape photographer can now prepare the plates at home in any number desired, stow them away in a valise, and taking with him a portable camera and folding tripod, start out on his labors unencumbered with chemical bottles and other endless supplies. Another and very important advantage arising from the discovery is the fact that the negative can be taken almost instantaneously, the Judge having secured faultless pictures of sailing boats in motion. Landscape views by this means do not possess the blurred look occasioned by the restless foliage. The artist now on his country rambles when meeting with a bit of scenery especially pleasing to his eye, can set the tripod, place it on the camera, draw the slide, raise the curtain, let it fall and the work is done. The plate is then placed away in darkness for treatment on reaching home, and the artist, with a loss of but three minutes' time, moves on to other scenes.

IMPROVED TELEGRAPH.—Prof. Klinkerfues, the director of the observatory at Göttingen, has patented a new telegraphic invention by which it is said to be possible to send as many as eight messages simultaneously along the same wire. A portion of the invention is an apparatus which simultaneously writes down all the messages as they arrive at the station to which they are addressed.

A DISCOVERY IN GUNNERY.—The *Pall Mall Gazette* states in brief manner these recent developments in gunnery: It has been very clearly shown that by chambering a gun, or, in other words, by enlarging the portion of bore containing the charge, and by increasing the charge of powder, a much higher velocity can be imparted to the projectile, and consequently the power of the gun greatly augmented, without increasing the strain on the piece. A six-inch gun, for instance, has been recently constructed, weighing only four tons, but firing a charge of 36 pounds of powder, with a projectile of 80 pounds, which has proved itself to be nearly as powerful a weapon as the nine-inch service gun, weighing 12 tons and firing 70 pounds of powder. In a paper published in the "Proceedings of the Royal Engineer Institute," it is stated that other guns designed on the same principle will shortly be constructed; and it is anticipated that one of the new pieces, with a bore of 10-inch diameter and about 15 tons weight, will be able to take the place of the 12½-inch or 38-ton gun as an armor piercing weapon in the forts. In order, however, that all the increase of power derivable from the adoption of this principle of chambering may be obtained, it is also necessary to materially increase the length of the bore to allow of the whole of the increased charge of powder being consumed in it; and this, the writer of the paper referred to suggests, furnishes another argument in favor of the substitution of breech for muzzle-loading ordnance. A 10-inch gun on the new system, for instance, will be three feet six inches longer than the service 12½-inch or 38-ton gun; and the extreme difficulty, if not impossibility, of loading so long a piece at the muzzle would preclude it being used in our casemates without crippling its efficiency by shortening the bore.

SLAG CEMENT.—Mr. Frederick Ransome, of England, has discovered that blast-furnace slag furnishes a cement which is free from the objections made to the Portland cement, when used for decorative purposes. From blast-furnace slag he produces a cement which is perfectly white, and in addition, possesses a strength greater than that of Portland cement. Although the new cement is colorless in itself, it is capable of receiving and retaining any tint that may be imparted to it, which is a valuable feature. The slag is reduced to sand or granulated and then mixed with from one to two parts by weight of chalk or limestone, and burned at a moderate temperature. The result is an excellent hydraulic cement, possessing great strength, and having a pure white appearance. Owing to the circumstance that the slag-sand has already undergone a process of burning in the blast furnace, the cement does not require so high a temperature to be used in its manufacture as it otherwise might. From a series of comparative experiments recently carried out with slag and Portland cements, it was found that samples of Portland cement two days old gave way at 510 pounds, whilst samples of Mr. Ransome's cement of the same age did not give way until 740 pounds had been reached. In another instance, a sample of the Ransome cement 21 days old gave a breaking strain of 1,440 pounds, whilst a sample of Portland cement seven years old only stood up to 1,327 pounds, and then broke. The samples were all one and a half inches square at the breaking point, thus giving a sectional area of two and one-quarter square inches.

EFFECTS OF PRESSURE ON VARIOUS SUBSTANCES.—It is stated that a member of the Belgian Academy of Science, Mr. Spring, has made some experiments on the effect of pressure on powdered substances. He is said to have subjected, amongst other things, a quantity of powdered poplar wood to a pressure of 20,000 atmospheres (about 280 tons per square inch). The result was a block having greater hardness than the natural poplar wood, and having a specific gravity of 1.328, while the natural wood has a specific gravity of only 0.389. There must be an error here in the statement of the pressure. Twenty thousand atmospheres would be 300,000 pounds, or only 150 tons per square inch. We understand that Mr. Edison has lately made some interesting experiments with high pressures. Among other things we are told that he has subjected alumina (clay) to a pressure of 80,000 pounds per square inch (40 tons), the result being the production of a substance so hard and sharp that it cuts glass.—*Scientific American.*

SILVERING MIRRORS.—An improvement in silvering mirrors, by which excellent results are obtained, and which at the same time spares the workmen the danger of exposure to the effect of mercurial vapors, has just been accorded a prize of 2,500 francs by the French Academy. The inventor is M. Lenoir, and his procedure is substantially as follows: The glass is first silvered by means of tartaric acid and ammoniacal nitrate of silver, and then exposed to the action of a weak solution of double cyanide of mercury and potassium. When the mercurial solution has spread uniformly over the surface, fine zinc dust is powdered over it, which promptly reduces the quicksilver, and permits it to form a white and brilliant silver amalgam, adhering strongly to the glass, and which is affirmed to be free from the yellowish tint of ordinary silvered glass, and not easily affected by sulphurous emanations.

Mining Share Market.

At the close of our last report (Oct. 9th) the market presented a dismal and discouraging aspect. The new week, however, began with reported improvements in the Union shaft, and removed some of the despondency, so far as favorite Comstocks were concerned. Rumors of rich strikes in the Sierra Nevada sent up that stock and Union Con., with a few others, but the feeling that perhaps the rumors were untrue sent them all back again to a slight raise over last week; and although the rumors have been changed into confirmatory reports of rich ore, averaging \$425 assay, and plenty of it, did not create the anticipated boom. The fears that have been raised from time to time by unauthenticated rumors heretofore cannot be allayed in a few days, even if the rich discovery of ore in the Sierra Nevada should prove a continuous reality. The public seem to be afflicted with the fear that porphyry is yet to put in an appearance, although a late dispatch says that there never was a better showing on the lode at the same stage of development. The main portion of the market, including the "hooming" stocks, has declined, apparently, to its normal condition. The trouble is laid at the door of the bears, although it would seem that assays of ore all the way from \$425 to \$1,394.40 would be able to at least steady the stock representing the mines turning out such rich ore, and avoid such breaks as have occurred for several days.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Tiger, Oct. 10th, \$26,000; Northern Belle, Oct. 6th, \$4,380.67; Martin White, Oct. 8th, \$4,703.15; Northern Belle, Oct. 8th, \$4,690.64; Christy, Oct. 13th, \$5,374; Alexander, Oct. 11th, \$7,713.53; Martin White, Oct. 12th, \$5,742.90; Oriental Con., Oct. 16th, \$2,323.54.

FREAK OF NATURE.—A singular freak of nature is shown in a marble mantel at the Cincinnati exhibition. In one of the onyx pilasters are seen the outlines of a woman's form, produced ages ago, when the marble first assumed its growth and consistence. Its discovery was the result of an accident. One of the workmen turned the pilaster upside down, and the strange beauty of the features of the face at once attracted his attention. His employers were summoned, and the pilaster reversed is now the chief ornament of the mantel.

GOLD IN COOS COUNTY, OREGON.—A remarkable discovery of gold is said to have been made outside the Coos Bay bar. The United States surveyors, while sounding on Sept. 25th, dropped their lead into 43 feet of water, bringing it up again covered with gold. There are good gold diggings on the beach opposite where this discovery was made. A dispatch from Empire City to the Roseburg Independent conveys this intelligence. It says: "There is no doubt as to the richness of the gold deposit discovered; it remains only to find a way to reach it."

In San Francisco half dollars are quoted at 99½ buying, 100 selling; trade dollars, 95½ buying, 96½ selling; Mexican dollars, 91 buying, 92 selling.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

VOLCANO ITEMS.—Ledger, Oct. 11: An engine has been brought up from Sutter Creek to run the drills in the big cut. The face of the tunnel is in the hardest description of rock, but it is likely that softer material will be encountered ere long, through which rapid headway can be made. Several miners lately engaged on the Sutter tunnel are employed on this undertaking. At the claim of Robinson & Jones there are 200 tons of first-class ore out, which is to be crushed at Robinson's mill at Russell's, two and a half miles from Volcano. This mill has been leased for the purpose of crushing the rock from this mine, the mill owner agreeing to put it in good order, and receive \$1 per ton for its use. Teasars now hauling ore from the mine to the mill at \$2.25 per ton. Two teams are kept going hauling ore from the Downs mine to the mill. R. Stewart is opening his quartz claim. He has a two-foot ledge of paying grade. A whim is in course of erection, and also a chute to convey the rock to the road. The Golden Gate and Confidence mines are yielding rock of paying character. Mr. Frye is prospecting a claim near Robinson & Jones', and has struck gold-bearing quartz. Bids have been sent in for building a 40-stamp mill for the Coney mine. The specifications call for the best class of work, and require the mill to be completed in 45 days.

BUTTE.

BANNER MINE.—Mercury, Oct. 10: A 15-stamp quartz mill and 40-horse-power engine have been received at the Banner mine, from San Francisco, during the past week, and are now being put up. The machinery will be located in the old mill building and the ore brought to it over a tramway. It is expected that crushing will be commenced in about two weeks.

CALAVERAS.

ITEMS.—The Chronicle in a late issue says: We have returns from a small lot of quartz taken from the Tom Phillips claim at West Point, owned by Reed & Co., that beat anything we have heard of lately, barring the great Sonora discovery. Six tons of ore yielded \$24 ounces of gold! Reduced to dollars and cents, that is in the neighborhood of \$275 per ton.

TOIRA.—Work has been resumed at this mine, which is located in Rich Orchards. The shaft is to be sunk another 100 ft or so.

GRISSEL CLAIM.—This mine is thoroughly developed to the depth of 1,500 ft. A new shaft is being sunk and other improvements made to increase the producing capacity of the mine.

INYO.

MONOCK.—Independent, Oct. 11: Official letter of Mr. Tibbets says: In south drift, 300 level, we are getting softer ground than for some time back; have but a short distance to run to reach ground started for. North drift, from No. 2 crosscut, 300 level, is going ahead well, keeping the ore on west side of drift. On account of air at this point it may be necessary to run a connection drift from crosscut No. 1 to No. 2, and in that event will probably run the air in the drift. This place continues to present some favorable showing as before mentioned. Crosscuts at 800 and 1000 levels are looking finely, and are in ore. Around in under drain has been hard this week, making rate of progress lighter than usual.

KERN.

NEW LEBON.—The Bakersfield Gazette of last week says: A mining discovery has been made about 15 miles above Kernville, near Kern river, west side, that promises to be valuable. Near the summit of the mountain at this point there has at some time been a lode that exposed a quartz ledge. This was discovered in June last, and located by Milton Kennedy and W. B. Rose. They immediately made a surface rock by P. Y. Baker, of Visalia, U. S. mineral assayer and surveyor, which yielded at the rate of \$24.11 per ton. The locators went down the hill below the surface croppings and started a tunnel to strike the ledge, and did strike it 90 ft from the mouth of the tunnel. They have every reason to believe that the ledge is very wide—over 20 ft—but as yet have only penetrated into it to a distance of 10 ft. The outside of the ledge is an inch or a half thick, is thickly studded with fine gold; but none can be seen in the rock, which is full of sulphurets. They had an assay made of rock taken from the ledge at this point by Mr. Baker, and it yielded at the rate of \$1,120 to the ton. The new mine is named "Young Guide," and is easy of access, with abundance of wood and water in the vicinity.

LAKE.

GREAT WESTERN Q. M. Co.—Lake Bulletin, Oct. 12: The Great Western Quicksilver mining company, near Middletown, are building a fine ore furnace of larger capacity. The mine is in splendid condition, producing six and seven hundred flasks per month. We understand that sufficient ore is in sight to run the mine for three years without further prospecting.

MODOC.

ITEM.—The Independent says: Cedarville is just at this stage of the discovery of a gold-bearing quartz ledge about eighty miles east of that place, near Summit lake. A great deal of "pocket mining" has been done in that vicinity, and a large quantity of gold has been taken out. A short time since a prospecting party was fitted out at Cedarville for the purpose of prospecting for a ledge, which was discovered as above stated. The ledge is said to be 50 ft wide and about 1,500 ft in length.

MONO.

MANMOTH.—Herald: A rich development of gold-bearing rock has lately been discovered in this mine. From what we learn, the last developments made were in the winze sunk from what is called the Sonoma tunnel, at a depth of 100 ft. The middle tunnel, which is now being run for the purpose of working the mine at a depth of 200 ft in this winze, and the work is being prosecuted with great vigor by the use of Ingersoll drills and compressed air. At the headway which is now being made, this rich body of ore will be struck within the next thirty days or less.

SOUTH MONDAY.—Bodie News, Oct. 12: New shaft has reached a depth of 30 ft, and are now engaged in timbering two compartments, 4x4 ft each, with timbers 10x10 inches.

DUDLEY.—It is anticipated that the Dudley ledge will be cut in 25 or 30 ft from the present face in the crosscut, which is now in 40 ft on the 400 level.

CON. PAPER.—The mine shaft has reached a depth of 352 ft. The 2-ft ledge found in the shaft week before last dipped to the east and out of the shaft early in the week, and day before yesterday another ledge about 6 in. wide brightly lively quartz was cut. This latter vein dipped east at an angle of 50°, and has already gone east of the shaft.

ANDREDA.—West crosscut on 200 level now in 64 ft, show 300 ft. The drift south is in 117 ft, still carrying the quartz formation. Crosscut west at the same level in 21 ft. At the 400-ft level the north drift is in 105 ft. Crosscut west, same level, is now in 32 ft. South drift from this level is now in 165 ft; crosscut east in 60 ft; crosscut west in 55 ft; ledge on this level looks remarkably well.

WEST PACIFIC.—The east vein struck show fine gold, and the character of the ore is such as to be found in the Coos Pacific, which lies adjoining the West Pacific on the east.

TRIUMPH.—A shaft 80 ft deep has been sunk, showing favorable vein matter.

UNIVERSITY.—Three compartments, well-timbered shaft completed 125 ft from surface. Iron-stained porphyry at bottom, and near of ore and quartz at that found in the Coos Pacific. Stringers of quartz are coming in which assay at high figures.

SOUTH BUTLER.—Drifting on the ledge at 350-ft level. Ledge at the point named 3 ft wide, of fair milling ore. Engine is drifting north from winze No. 2, work showing ledge 5 ft in width of very good ore.

BODIE BLUFF COX.—Incline down 75 ft on vein. Ore on hanging wall very rich.

BONIS TUNNEL.—In 1,225 ft near Bechtel line.

B. C. & L. C. JOINT SHAFT.—In 110 ft, and well timbered. Ledge 2 ft wide, of good milling ore.

SIERRA NEVADA.—Oct. 11: The combination shaft is now 400 ft. The east drift is in 120 ft; north drift, 225 ft. The mine is looking well in every particular.

BLACKHAWK.—Rock in bottom of shaft has changed to vein formation.

TIOGA.—Outside the loss of life, the damage at the works by late accident, amounted to a trifling.

MONO.—The east crosscut is in 505 ft east of the shaft. Have drifted north from this crosscut 120 ft, and the formation passed through shows that it is on top of the ledge, and some good ore has been taken out.

RED CLOUD.—Five-ft ledge of fair ore in drift on 250 level. Upraise from same drift in 3-ft ledge better ore, although low grade.

BALTIMORE MINE.—Lake Mining Review, Oct. 11: The tunnel run by the company has tapped the vein at a depth of 100 to 134 ft from the mouth, and is now in the vein 5 ft, all gold milling quartz.

NEVADA.

NEW STRIKE.—Herald: John Grimes, who recently purchased the interest of Mr. Ragan in their union in Mr. Grimes' field on Gold Flat reports having struck rich rock. The ledge is about 20 inches thick.

GRISSEL CLAIM.—The claim of Grissel & Wing, located in the head of the Yuba river, above Washington, keeps panning out well in coarse gold. Last Saturday they found another rich crevice and took out 60 ounces of fine nuggets. The next morning they took out 20 ounces more.

ITEMS.—The Kansas, New York and Live Yankee mines are being prepared for working machinery to be put in.

RICH STRIKE.—F. Byrne, Esq., brought a sample of rock to the Herald office last week, which was taken from the old Corinth ledge, on Gold Flat, near the El Capitan mine. The rock showed very rich in free gold, which was to be seen in the form of threads, beads and leaves or scales. Some of the best ever taken of an inch across and almost as thick as tin. These were found all scattered through the decomposed quartz, which came from the edge of the ledge as it was picked apart. The mine has been renamed the Gold Leaf. The rock carries some sulphurets, which are very rich. The vein is from a foot to 13 inches thick. The shaft is down nearly 50 ft. About two tons of rock have been taken out.

NEW LEAN.—Transcript: Mr. Gillespie has made a remarkable strike in his shaft on the Cornish ledge, 300 ft north of the railroad track and 400 ft east of the Town Talk tunnel. The shaft has a depth of about 40 ft, and for some time past the ore from the north and south drifts has been paying from \$15 to as high as \$50 per ton. This week he commenced working in another portion of it, and on Wednesday developed a 2-inch body of ore, through which runs a lead an inch thick of what is described as being "solid gold."

WASHINGTON MINING DISTRICT.

TIDINGS.—Oct. 11: The Yuba gold mining company have struck a ledge in the cross-cut recently started, but from the distance run, as compared with surveys made, it is not supposed to be the main ledge for which the drift is being run. The quartz is said to be of fine quality, and is getting things in shape for winter. The Last Chance mine is looking well.

We saw a lot of rock from this mine this week, and it is as rich as Bodie's choicest, but it is so near home that little attention is paid to it. The ledge is 3 ft thick in the drift and is rich. The Bessie Miller company is driving the main tunnel and, it is said, finding good looking quartz.

On Portman's creek the new company for which McGraw is mining is finding very rich rock.

MURCHIE MINE.—Transcript, Oct. 14: Among the improvements that it is understood the management of the Murchie Quartz mining company desire to make soon, are the erection of a new 40-stamp mill and hoisting works. The latter would be put up 300 or 400 yards southwest of the one now in use, where it is believed an incline can be sunk so as to reach the ledge without first running the drifts through solid rock that are, at present, found necessary. The hoisting works now standing are not in a good condition, therefore a double reason exists for putting up new ones. The old mill works well, but will probably be kept where it is in case the improvements named are made, as it is thought enough rock can be taken out in its vicinity to keep it going.

PLACER.

PROMISING GRAVEL MINE.—Argus: Robert Shannon has a promising gravel claim of 40 acres down on the American river, about a mile and a half from Auburn station. He has a tunnel running in about a hundred ft, from which gravel is taken that shows very many colors to the pan.

GOOD ORES.—The McLeod brothers and two other men, all residents of Penryn, recently struck what they believe to be a good paying claim near the old Stewart's Flat quartz mill, about a mile southeast of Penryn. Some of the rock was taken to a custom mill at Ophir and crushed. It yielded something like \$27 or \$28 per ton.

RICH STRIKE.—Herald, Oct. 11: Frank Hoffman, an old resident of Michigan Bluff, has recently made a gravel strike on what is known as Sage hill, about a mile from the bluff, that is very rich. He washed out a number of pans, after striking the gravel, for the purpose of prospecting it, and from one pan, the last one washed, he realized \$25.50. This is a 49 lead, and has every indication of being extensive.

PLUMAS.

ORENEVILLE MINE.—National, Oct. 11: The Plumas National Co. is now working this mine through the No. 2, or lower tunnel, having opened up direct communication by a tramway. The ledge now being worked by the company, as developed by the lower tunnel, presents a beautiful and remarkably regular and perfect as a fissure vein can show. The mine at this depth is being opened up very rapidly, and the quantity of ore shown in the various stopes is immense—the main stope exhibiting a body of ore over 10 ft wide. The sulphurets are being concentrated in the mill by the Hendee process, and it is reported that they assay very satisfactorily, and that the company will erect the necessary furnaces to roast and reduce them.

GREEN MOUNTAIN MINE.—A very fine quality of ore is being mined from what is termed the Grass ledge. This mine has a No. 3 or lower tunnel, some 1,800 ft in length, which, at about 1,200 ft, cut a large, fine body of quartz. This has developed into a big ledge, and is well opened by stopes. Work is pushed ahead in this tunnel, the intention being to strike the main ledge at this depth. From such a tunnel an incline shaft is down 80 ft on the ledge, and the main or lower tunnel is making for this point. The two mills of the company are running on full time.

ITEMS.—The Mexican mining company, in North canyon, has a tunnel in about 800 ft. They have a good ledge, and have extracted some excellent ore. Their mill is running regularly, and the work is being done satisfactorily. The New York mill has been recently started again, after being moved to a point nearer the present workings of the mine. A company has been formed recently in Greenville to develop a large gravel claim across the ridge north, towards Mountain Meadows.

SIERRA.

NEW LEDGE.—Messenger: The Tiger Quartz Ledge, located at Shaville near the Ploocene shaft, at the head of Rock creek, is the latest development in the quartz line in this section. Some time since, Henry Winters and others, knowing that considerable gold had been taken from the ledge in years gone by, determined to prospect further in the vicinity. They dug a shaft, but had only sunk about four ft from the surface when they struck a ledge six ft wide, the rock from which yields \$3,750 per ton. Considerable work has been done here in the way of running tunnels just under the surface, but for some

reason the claim was abandoned, and no labor has been performed for the past ten or fifteen years. The ridge on which the location is full of quartz, and a half a mile further east than Shaville persons made large waves some years ago by sinking shafts and carting the dirt to Rock creek to be washed, the gold being in the loam, and but a few feet below the surface.

TULARE.

NEW DISCOVERIES.—Delta: We hear of a promising silver lead discovered by William Toomey, on the county line of Tulare and Fresno, near Mill creek, on the ranch of Martin Parsons, and 60 rods from his house. Toomey and Parsons have located 1,500 ft each. The lead just below the surface is three feet wide. Assay of croppings, \$50. Discoveries of rich ore-bearing rock are reported about 45 miles from Visalia, north of King's river, in the foothills. Assays range from \$25 to \$500 per ton, gold and silver. Several claims are already located, and on one work is being vigorously pushed.

NEVADA.

WASHOE DISTRICT.

OPERA.—Gold Hill News, Oct. 13: The crosscut west on the 2400 level is now making better progress, averaging three ft per day, and passing through favorable-looking vein material carrying stringers of quartz; total length from the east side of the incline, 50 ft. The east crosscut on the 2300 level has reached a soft vein formation which requires no timbered shaft, reducing progress to two and a half ft per day; total length, 110 ft. This formation also carries stringers of good-looking quartz together with clay. The connection between the joint workings from the 2100 and 2300 levels is being enlarged to the full size of the winze and timbered. The drift following the Hardy vein on the 2100 level is making two ft per day through good ore; total length from crosscut No. 1 to the Hardy vein, 110 ft. The drift on the 2000 level of the joint Mexican crosscut west on the 2000 level, the face being in bitulose porphyry carrying streaks of quartz; total length, 240 ft.

SIERRA NEVADA.—The drift south and west from the 2300 station of the incline has been timbered up, and is going ahead again slowly, the formation penetrated needing to be timbered as opened up. This drift has run 25 ft into very rich ore. The ore body is crossed by stringers of ore still richer, and the face shows no falling off in the quality. The drift is being run for the Union shaft, with which it will connect, and is following the course taken by the diamond drill run some two months ago. The drift east from the east shaft, 2300 level, is now in 130 ft, the face in hard, blasting porphyry.

JOY VINCENY.—The south lateral drift, 850 level, and running from the joint crosscut, is now 10 ft in length, the face in a vein formation of clay and quartz and looking well.

MEXICAN.—The joint Union crosscut west on the 2000 level is again in soft vein matter, having cut through the rib of hard porphyry recently encountered; total length, 105 ft. The joint winze from this level is now down 130 ft, and continues in soft vein matter carrying considerable water.

UNION SHAFT.—The shaft has attained a depth of 70 ft below the 2200 level of the Sierra Nevada—2300 of the Union—the bottom continuing still in ore and improving as depth is gained.

GOULD & CURRY.—The joint east crosscut on the 1700 level is in 1412 ft from the main lateral drift, the face in porphyry. The drift is some 300 ft east of the Souther shaft. The whole distance from this shaft to the new joint shaft is 2,235 ft.

CALIFORNIA.—The stopes in the ore vein, 2150 level, have been carried up 35 ft, the upper floor still in good ore. The north drift on this level has followed the ore vein 55 ft, and it still holds its width of four ft of good milling ore in that direction. The lateral drift from the joint crosscut on the 850 level, being carried down, total length, 63 ft, the face in the vein matter consisting of clay and quartz, and looking well.

CONSOLIDATED IMPERIAL.—The joint Alpha crosscut east, 2600 level, is being driven rapidly forward through good-looking vein matter; total length, 125 ft.

LADY BRYAN.—The south drift, same level, is now in fine-looking quartz, assaying from \$8 to \$7. The drift west from the drift south, 600 level, has followed the ore vein 55 ft, and it still holds its width of four ft of good milling ore in that direction. The lateral drift from the joint crosscut on the 850 level, being carried down, total length, 63 ft, the face in the vein matter consisting of clay and quartz, and looking well.

ANDRES.—Drifting east on the 350 level, and encountering some places of ore. The drift along the ledge from the base of the winze and 60 ft below the 400 level, is in a formation of quartz and porphyry mixed.

WARD.—The shaft has reached the depth of 1,750 ft, the bottom being in hard rock. The flow of water is still heavy. The east crosscut, 800 level, is 920 ft, and without any marked change.

DUN GLEN DISTRICT.

ROYAL EAGLE.—Silver State, Oct. 14: This is a newly discovered gold-bearing quartz ledge at Dun Glen. It crops out 10 or 12 ft high on the mountain, but as it was exceedingly large and covered with moss none of the hundreds of prospectors who passed by it since the district was organized ever suspected that the bluff was quartz, and literally spangled with gold. When Thomas left Dun Glen the discoverers had drifted over 20 ft into the bluff at right angles with the course of the ledge, and were taking out quartz that will average at least \$100 to the ton. The specimens which he brought here were broken from a boulder which a blast had thrown down the hill, and free gold is visible to the naked eye all over them.

Thousands of thousands of tons of quartz in sight, in all of which free gold is visible.

EUREKA DISTRICT.

SILVER CONNOR.—The Sentinel says: Four men are employed in this mine, and the monthly yield aggregates about \$2,000. The ore runs from \$30 to \$250 per ton, chiefly in gold. There is an immense mass of lower grade ore in the mine, which cannot be handled profitably at the present price for transportation and reduction. The Silver Connor is one of the best paying mines in the district.

HOOSAC.—Mr. Lesser informs us that the late development of the Hoosac mine is still improving, and is fair to widen into a bonanza of good size. The ore is of high grade and carries less base material than the ore obtained in the old workings of the mine. The Hoosac boys are feeling much encouraged over the prospects of their property.

JACK RABBIT DISTRICT.

DAY MINE.—A. S. Ould, Sup't, in his official report of Oct. 10 in the Ploocene Record, says: Our work of quarrying out will be finished to-morrow, and as I have now many of necessary timbers on the ground I shall be ready, I hope, to commence sinking on Monday or Tuesday next. We will go down directly through the ore body. Owing to the fact that we need better ventilation I have concluded to make a connection from the black winze to our present working, which can be done in probably a week. Our prospects and showing are still of the most encouraging character. I am firm in the belief—firmer than at any time before—that we have an exceedingly valuable mine, but the company must be a little patient till I get things in shape so as to work advantageously. We are not breaking ore at present for the reason that our ore house and platforms are full.

PATTERSON DISTRICT.

RENEWAL OF WORK.—Ploocene Record, Oct. 11: We learn that mining operations will shortly be renewed in this old abandoned mining district, which some years ago attracted considerable attention, but was finally abandoned and the buildings of the town were torn down and hauled to this place. For the past four years the ranchers in the neighborhood have been devoting their spare time to prospecting in the Patterson district, and have discovered and opened up some very promising ledges, and through the aid of an agent have succeeded in getting parties in

[CONTINUED ON PAGE 252.]

Carbonate Belt of Colorado.

Frank Fossett, in his interesting book entitled "Colorado, Its Gold and Silver Mines," etc., after giving a history of the rise and growth of Leadville, describes the formation and characteristics of the carbonate belt in that region. He says:

The Arkansas river flows in a southerly direction for some distance from its sources among the lofty Sierras. The valley that encloses it is bordered by the great Continental Divide on the west, whose peaks for 100 miles average over 14,000 feet high, and the almost equally elevated Mosquito or Park range on the east. Both of these mountain systems unite near Mt. Lincoln and the head of the easterly fork of the Arkansas. Below the held and barren crest of the Mosquito range are what might be termed its foothills, sloping west to the Arkansas valley. Among these heavily-timbered hills is the famous carbonate belt, and through it California, Stray Horse, Evans and Iowa gulches lead westward down to the main stream. The Mosquito or Park range separates the Arkansas valley from that great natural basin of the "Rockies" called South Park. Leadville is on an inclined plane, sloping west and at the base of the carbonate hills, 10,025 or 10,200 feet above the sea.

The course of the carbonate zone or belt is north and south, and the general dip of the ore is eastward and from 12° to 25° downward from the horizontal; but there are numerous faults and displacements, as with the overlying porphyritic trachyte and underlying limestone. Above the porphyry may be more or less "drift," and below is the limestone formation, quartzites, crystalline schists and granite, tilting downward one below the other, but occasionally pushed out of place.

The direction of the ore deposits is often changed from the ordinary incline to the vertical, or to wave-like depressions and elevations corresponding to those of the limestone. The depressions contain most of the richer ore when it is in ordinary or thin layers. The underground workings are often like so many irregular steps and landings, making the construction of a regular incline finally necessary for large production and advantageous operations in the mines. The limestone forms the footwall, on which the contact deposits have been made, and the porphyry the hanging wall. In places the porphyry is found under and beside the ore for short distances.

The veins or deposits so far opened have varied in thickness from the thinnest kind of a seam to several feet. There are claims that show 10 feet of mineral, and a few have ore bodies 20 and 30 feet thick. The quantity of the valuable metals contained varies greatly, and, unlike most other districts, the largest deposits are as likely to be among the richest as any other way. Most of the ore is so soft as to require no blasting—the pick and shovel being sufficient to remove it.

It has been said that Leadville district defies all previously developed rules regarding mineral in place or in deposit. Mineral is found by sinking shafts, and not by the outcrop, as in mineral veins elsewhere. The objective point is the contact of the porphyry and limestone, for between those formations the mineral is almost universally encountered, if found at all. Below the porphyry is the iron, which is a sort of cap rock to the ore, and is called the contact. Below this, if no ore is found, and otherwise beneath the ore, usually occurs the blue limestone, in undulations like a disturbed sea. If no ore is visible at such locations, the miner drifts on the contact to the right or left, or in any direction, with the hope of finding less barren localities beyond. Rich ore bodies have been found by drifting when none were manifest at the bottoms of shafts.

It will be seen that this prospecting for ore by "sinking" is attended with a great deal of uncertainty, and this uncertainty not only pertains to the ultimate results, but also to the depth necessary to go before anything definite can be ascertained. In some places the contact has been found at depths of 30 or 40 feet, and in others it was more than 200 feet below the surface. It is generally conceded that four distinct stratifications, veins or mineral layers, have been developed in the Leadville carbonate district; that these stratifications extend in a northerly and southerly direction, and dip eastward into the mountains at an angle of from 15° to 25° below the horizontal.

The ore yields from a few ounces of silver per ton in some localities to 50, 100 or 200 in another. Bunches of \$1,000 and \$2,000 ore have been found, but they are not extensive. The proportion of lead is almost as variable, ranging all the way from a few per cent. up to 70%. Ore rich in silver is more likely to be rich in lead than the reverse. Many claims have been opened that are too poor to work, and others contain horridly rich and poor ore. The average contents of the ores handled for many months by the ore buyers and shippers were from \$100 to \$170 in silver, and from 20% to 40% of lead. This was since the Fryer Hill mines began to produce so largely. Their output raised the average value per ton of the total yield of the district. But while these figures represent the ore shipments, they were far above the yield of ores treated in most of the smelters. In some of these five tons of ore usually resulted in one of lead bullion, carrying 250 ounces of silver, indicating that 20% of the ore was lead, and that it carried 50 ounces of

silver per ton before smelting. Ore that contains 100 ounces of silver and 25% lead would have a silver valuation of about \$113, and a lead valuation of about \$17. This refers to the value of the ultimate bullion product, not to the selling or buying price of the ore. Much vein matter is left in the mines or on the dumps that is too poor to handle. This carries silver and lead in varying quantities from \$50 down to \$5 per ton. Some carbonate mines yield gold in small amounts.

There are carbonates of lead, with some galena, various oxides of iron and manganese, and small amounts of chloride of silver. There are what are called "hard carbonates" and "soft carbonates." Some of the latter have the appearance of moist sand, or the material that railroad grades are made of. Some are gray and others stained red or black with oxide of iron or manganese. The hard carbonates are of different colors, but generally have a variegated gray appearance. The oxides of iron are rarely as rich as the heavy lead carbonates. Leadville district is noted for qualities always desirable, but seldom found combined, such as rich mineral in enormous quantities, easily and cheaply mined, and capable of being reduced at a small expense. These are the causes of the pre-eminence of some of the leading mines over most others that the world can show.

Friction and Lubrication.

Prof. Thurston, of the Stevens Institute of Technology, etc., London, points out that any substance to be efficient as a lubricating material must possess the following characteristics: 1. Enough body or combined capillarity and viscosity to keep the surfaces between which it is interposed from coming into contact under maximum pressure. 2. The greatest fluidity consistent with the preceding requirements—that is, the least fluid friction allowable. 3. The lowest possible co-efficient of friction under the conditions of actual use—that is, the sum of the two components solid and fluid friction should be a minimum. 4. A maximum capacity for receiving, transmitting, storing, and carrying away heat. 5. Freedom from tendency to decompose, or to change in composition by gumming or otherwise on exposure to the air, or while in use. 6. Entire absence of acid, or other properties liable to produce injury of materials or metals with which they may be brought in contact. 7. A high temperature of vaporization and of decomposition, and a low temperature of solidification. 8. Special adaptation to the conditions as to speed and pressure of rubbing surfaces under which the unguent is to be used. And 9. It must be free from grit and all foreign matter.

As the result of the study of the facts which he has ascertained, and of the consideration of the many hundreds of experiments made, the Professor shows that the great cause of variation with well cared-for journals is alteration of pressure, and it is seen that the higher pressure within the range of these experiments give the lowest percentage of loss of power by friction. The value of the co-efficient is seen to be greatly modified by the state of the rubbing surfaces; and the necessity of keeping journals in perfect order cannot be too strongly insisted upon. A single scratch has its effect in wasting power. A journal should have its surface as smooth and as absolutely uniform as a mirror: every well kept journal has such a surface. The resistance due to friction varies with velocity—rapidly at very low speeds, as from one to ten feet per second, and slowly as higher speeds are reached until the low changes and increase at ordinary temperatures takes place, and at a very low rate throughout the whole range of usual velocities of rubbing in machinery. The consumer, he says, will usually find it economical to use that lubricant which is shown to be the best for his special case without regard to price, and will often find real economy in using the better material sufficient to repay excess in the total cost many times over. The semi-fluid lubricants are usually the most economical, in consequence of their peculiar self-regulating flow as the rubbing parts warm or cool while working. Where heating is not to be anticipated maximum economy is obtained by the minimum rate of supply allowable, only if that supply be maintained with absolute uniformity.

The necessity of a lubricant as is well known arises from friction which is always present when two bodies or particles whether solid, liquid, or gaseous are compelled to move one upon another, rolling and sliding friction with solids, and fluid friction with liquids and gases. Fluid friction is found to vary with the square of the velocity, and is proportional to the area of rubbing surface, and is probably independent of the pressure. In hundreds of experiments with pressures varying from 5 to 275 pounds to the square inch he has found the friction of well lubricated journals to vary in such a manner as to prove that the law which governs such cases is quite different from that which applies with dry solids. When a lubricant is interposed between the rubbing surfaces of a revolving journal and its bearing, or between a sliding plane surface and its support, if acting effectively, it forms a fluid cushion, separating the surfaces more or less perfectly, as it is more or less viscous, and as capillarity is greater or less, thus giving the resistance to motion more or less of the character of fluid friction.

North Carolina Gold Region.

That portion of the State of North Carolina where the precious metal exists, according to F. R. Page, in the Boston *Economist*, is a slightly undulating country, rising slowly to the northwest to the foothills of the Blue Ridge, and embraces the upper and midland counties. The central portion is from 850 to 1,050 feet above the level of the ocean. The geological formation is granite and slate, modified in syenite, porphyry, gneiss and argillaceous shale, chloritic, talcose and mica slate, with dykes of trap-rock. A great drawback to mining is the difficulty experienced in separating the gold from the sulphurets of iron and copper with which it is associated, the quicksilver only picking up a very small percentage of the assay value by any of the processes now employed there.

The machinery consists of the Chilian mill for crushing and grinding, the drag mill, and the Burke rockers. A few mines have a stamp battery with copper plates.

The Chilian mill consists of a saucer-shaped stone, from six to ten feet across, hollowed out to receive the charge of ore. Two circular millstones, about one foot thick, are set on edge. There is a vertical shaft from the center of the first stone with another at right angles, passing through the center of the millstones, and extended out to one side. A mule is attached to the extended shaft to give motion to the millstones.

The drag mill has a similar stone hollowed out, with vertical shaft from center. There are arms to this shaft, to which round stones about one foot in diameter are attached by chains. When the shaft is turned, these stones are dragged around, and the charge ground and amalgamated.

The rockers consist of a trough about ten feet long, and two feet in diameter, dug out of a large pine tree, and the upper end stopped up, and a box with a perforated sheet-iron screen is set to receive the ore. Every 18 inches a channel is gouged out across the bottom of this trough. Between these channels a thin copper plate is tacked and quicksilver placed in them, also on the copper plates. Two crotch stakes are driven in on each side of the rocker, with a horizontal rail resting in the crotches. One negro shovels in the pulverized ore and water at the upper end, while another sits astride the rail and with one foot on one edge of the rocker, the other foot on the other edge, he keeps the rocker in motion.

No one has ever treated these sulphurets here by crushing, roasting, washing and pan amalgamation, or by the chlorine process, nor has much ore been sent away to reduction works. As the gold is mechanically combined with iron pyrites, great care must be used in roasting, or the charge will fuse and cake, or the gold be carried away by the rapid combustion and smoke from the sulphurets. By this means 25% of the gold may be lost.

The gold in the roasted product will be partly covered with the oxides of iron formed, and prevent the quicksilver from taking up the portion so covered, and causing another loss. The addition of salt to the charge during the last of the roasting helps to clear these particles of gold, and a larger per cent. is obtained than by roasting alone.

By the chlorine process the roasted ores are put in a wooden tub and chlorine introduced at the bottom, until the gold is all chloridized. The tub is then filled with hot water and the chloride of gold dissolved. This liquid is then drawn off, and the gold precipitated as a brownish black powder, which has to be refined by heating with borax and soda.

This process, although more expensive than roasting and amalgamation, is probably the best for North Carolina sulphurets, as they contain but a small per cent. or trace of silver, and the iron pyrites, holding the gold, carries only a small per cent. of copper or none at all.

The sulphurets in some of the mines assay from \$100 to \$550 per ton in gold, and those from others could be concentrated to the same value or higher. Such rich sulphurets would pay to mine and sell, or would warrant the erection of proper reduction works to treat them there.

Inexperienced men have wasted capital here, receiving no returns, and very few mines in the section have been worked with any system.

NEW MEXICAN SILVER MINES.—The New York *Tribune*, of late date, says: The intention of the Mexican government to assume control of the silver deposit in the Mohada or Dewey mountains, serves to confirm the report that a rich mineral district has been discovered there, producing ore that yields sometimes as much as 800 ounces of silver to the ton. The contemplated scheme may also be connected with the fear expressed by the Mexican journals that a rush to the mines from Texas will create a spirit of territorial annexation. As the district is within only 200 miles of the frontier, some Texans may desire to see it and the intervening territory added to their State; but if they acquire protection and comfort under the Mexican flag, they are not likely to abandon mining in order to engage in filibustering schemes. If, however, the deposits are as rich as reported, the people from this and other countries will not be deterred by Mexican misgivings from working them.

Spontaneous Fracture of Castings.

We took occasion in an article on the above subject, in a previous number of this paper, to refer to some of the causes which induced fracture in castings which must be attributed to spontaneity, or, rather, to the change of density from a heated to a cold condition, dependent more or less on its shape. We allude to the matter again because Mr. T. Wrightson, in a paper recently read before the British Association, throws additional light upon the atomic changes that accompany the cooling and contraction of cast iron. He has been able to determine, by experimenting upon the pressure of buoyancy of an iron sphere immersed in a bath of molten metal, that the maximum density of cast iron occurs when cold, and that its minimum density occurs when in the plastic condition just before liquefying or solidifying. This result clearly indicates that after a casting has been poured into a mold, it expands in volume at the moment of solidification, and from that point the contraction and density of the metal proceeds very rapidly, until quite cold. In the case of the cast-iron pulleys, then, the thin rim, presenting a large surface for radiation of the heat, and being also at the exterior of the mold, proceeds whilst cooling, first to maximum expansion, and then to contraction, without danger to itself, except from the rigidity of the mold, as the arms would be still in a plastic condition, and would offer no resistance to contraction. This allowance for contraction, in the non-rigidity of the mold, is usually so well understood nowadays, that few breakages of castings occur on that account. The cores, subject to the compression of contraction, are duly constructed, in part of straw or other inflammable material, so as readily to give way under the contracting pressure of the casting.

The case is, however, very different with the arms of the pulley if straight. These, in the usual course, reach their maximum expansion, i. e., the moment of their solidification after the rim has contracted and set. The arms are thus "jumped" or shortened upon themselves at this period, and after this point the contraction sets in rapidly. But the arm of a two-foot pulley, forming a straight diameter across, must now contract nearly a quarter of an inch in linear measurement, whilst each of its ends is securely held by the already rigid rim. A fracture in one of the arms to allow free contraction is the obvious result, and when one arm has parted, there will be no reason for the other in the same diameter breaking. In some cases a large portion of this irregular contraction may take place without fracture by the metal "drawing" in places, generally where the arms join the rim or boss. The formation of the arms of pulleys in an "S" shape is for the distinct purpose of avoiding this danger from irregular contraction. The "S" arm, not being a rigid diameter, is more or less capable of adapting itself, by a change of shape, to a smaller contracted dimension. It is, however, remarkable how many founders still neglect such a simple precaution even as that.

A similar case to that of a pulley, as described above, for a long time caused considerable trouble and expense to a manufacturing firm. The casting was a frame for horse gear, consisting of an outside square frame, with four diagonal ribs supporting the boss in the center. The castings almost constantly broke, either before leaving the foundry, after reception into the erecting shop, or after delivery to the customer, and always in the same manner. Each of the diagonals fractured across one of its ribs, thus plainly showing it was the result of internal contraction. Sound castings were afterwards easily obtained by observing the precaution to part the exterior frame into two distinct portions, so that they could freely give to the internal contraction of the diagonal ribs.

A case of much interest, causing a long and serious arbitration, arose from the fracture, amongst other causes, of the inner shell of a steam jacketed cylinder of large diameter. The cylinder had been cast in one piece with its jacket, and, apparently, had no particular care paid to its cooling in the foundry. The result, in the light of the foregoing explanations, was unavoidable. The external jacket being situated in an exceptionally good position for the radiation of its heat, naturally cooled long before the internal cylinder shell, which could only cool by radiation towards the core. When, however, the internal shell cooled and contracted, its ends were each firmly attached to, and formed a part of, the already rigid exterior jacket. The result was evidently a condition of extreme tension in the interior cylinder shell endeavoring to part from the exterior shell or jacket. The metal of the cylinder was exceptionally good, so the interior shell had been able successfully to withstand the very considerable tension until after the engine had been put to work. Then the varying temperatures to which the cylinder was subjected, sometimes colder and sometimes at a temperature of about 300° F., at last caused the overstrained atoms of the interior shell to part, at one end around a portion of the circumference, and in the center around the other part of the circumference.

Embarassing accidents frequently happen in the fracture of the valve boxes of deep-lift pumps, the casting here being peculiarly liable to irregular contraction. The remedies against such accidents are evidently two in number. First, to so construct the casting that its form shall be capable of yielding to such irregular contraction should it take place, and that the

equal sections of metal used shall ensure uniformity in cooling; and second, to take such precautions in the foundry that the casting shall cool equally throughout by the artificial cooling of such parts as may naturally remain hottest the longest, or by the artificial heating of such parts as may cool too rapidly. It should be remembered as an axiom that no irregular tension will be set up if the casting can be made to cool uniformly and isochronously throughout.

Homer District, Mono County.

This new mining district was formerly a portion of Tioga district, and is situated at the head of Mill creek. The Bodie News, speaking of a recent visit to the district, says: The road from Bodie is either by way of Cottonwood canyon or the Mormon Ranch, the latter being preferable, and the distance to the lake is about 22 miles. From Mormon Ranch the road leads through Keith to South Bodie district, leaving Summers' Ranch on the right, and thence to the canyon known as Mill Creek canyon. The grade leads up for a distance of three miles, and is one of the easiest to be found in the mountains. On either hand rise up huge boulder-covered mountains, showing unmistakable evidences of the glacial action of centuries, which, in their frozen course, have left boulders and rocks of all sizes along their route, embracing all varieties of the mineralogical kingdom. A rushing, roaring torrent of pure foam-crested water makes its impetuous way down the canyon and is lost at last in the alkaline waters of Mono lake, some six or seven miles below. Following along this picturesque mountain torrent, we come to a view of almost unrivaled magnificence and grandeur. Nestling in the depths, made probably by some historic crater of an extinct volcano, we find an expanse of clear mountain water, named Lake Wasson, from our new member of the Legislature, Hon. Joseph Wasson, whose placid depths make homes for thousands of the finny tribe. This sheet of water is one mile long and about one-quarter of a mile broad, and is supplied and kept full to overflowing by a continuation of the stream found below. At the foot of this beautiful spot we found camped several adventurous prospectors and others, among whom we noticed Judge Owen and James Mathews from Bodie, who had taken time by the forelock and pre-empted a mill and town site, as also located several fine apperling ledges in the mountain beyond. A trail leads along the bank of Lake Wasson to the home of Mr. Landy, which we found to consist of a home-like log house surrounded by a large growth of pine and tamarack. After a long and dusty ride, this oasis in the desert was doubly inviting. Away up 4,000 feet above the level of Mono Lake rose towering and bald-faced crags over crage, until they ended only when the granite-capped apex was reached. The country rock consists of quartzite, granite and slate, the granite forming the cap-rock—and the mineral is found in enormous veins at the very surface of the ground. The May Landy, the newest sensation, is located away up on top of the mountain, and specimens from there show free gold in large quantities. The ledge, as uncovered, shows a width of two and one-half to ten feet, and free gold is found in the rock in abundance. The direction of the ledge is about north and south, and it can be traced for a length of four miles. Numerous locations have been made, and the 40 or 50 prospectors in the district seem highly elated over the future of the camp. Wood and water are in unusual abundance, and mining can be carried on by means of tunnels with much less expense than elsewhere. Without doubt, the surface appearance of the district is such as to warrant the investment of capital, and already several mining speculators have made arrangements, by bond and otherwise, for opening up claims there. The immense placer fields which are found extending all along down the canyon leading to the mines were worked with most successful results many years ago, and still exist as evidences that great quartz ledges are to be found somewhere in the near vicinity. For years other and more enticing fields have attracted the miners away from this section, and the impossibility of getting in supplies in the winter months, and the expense attending the same during the summer, have detracted much from the really meritorious nature of this section of Mono county. Now, with easy communication, and a firmly fixed market at Bodie, there can be no doubt of the eventual greatness of Homer district as a mining center. A road has been surveyed along the shores of the lake, and with the expenditure of money could be continued over the Sierra Nevada to the Yosemite valley—only 35 miles distant—thus making a feasible route for tourists in the season. The climate is milder than at Bodie, and we are told by old residents of the vicinity that the snow never lays so long or so deep there as elsewhere in the county. Game is said to abound in the hills and valleys, and cereals can be raised with success and certainty. Near Mill creek is Summers' Ranch, where this season has been cut \$40,000 worth of hay, the ranch being valued at \$60,000. Vegetables also grow in abundance, and thousands of acres of land lie awaiting the manipulations of the husbandman.

NEW METALS.—Eleven new metals have been discovered within the last two years which have received the following names: Davium, moeandrium, phillipium, ytterbium, decipium, neptunium, lavæium, norwegium, uranium, scandium and thaumasitic.

USEFUL INFORMATION.

PRUSSIAN BLUE FROM RED OXIDE OF IRON.—It is well known that Prussian blue is ordinarily manufactured from the protosulphate of iron and ferrocyanide of potassium, by which process a pale blue precipitate is at first obtained, which acquires the characteristic dark blue tint by exposure to the air, whereas, the persalts of iron when treated with the ferrocyanide of potassium at once assume the desired dark blue color directly the respective salts come in contact with each other, and Mr. Alex Watt, of Battersen, has taken advantage of this well-known chemical fact in working out his improvements, the object of which is the treatment of native red oxide of iron by chemical and mechanical means, whereby is obtained economically certain products which are useful in the arts—Prussian blue, jewellers' rouge, and a red pigment suitable (when mixed with oils and such usual ingredients) for coating iron and other surfaces. For the purpose of his invention he treats red iron ore (peroxide or sesquioxide of iron) with strong hydrochloric acid, and with the assistance of moderate heat, whereby he obtains a very rich solution of peroxide of iron at a very moderate cost. The solution thus obtained is afterwards diluted with water, and the Prussian blue precipitated in the ordinary way by ferrocyanide of potassium. The blue pigment is then washed and treated as usual.

REFRACTORY BRICKS AND FURNACE LININGS. A new material for basic linings and bricks has been recently made by S. G. Thomas, of Battersen Park, England. He mixes lime with liquid tar, so as to moisten it and render it somewhat plastic. When the silica and alumina are low a little oxide of iron may be mixed with the lime before adding the tar, the oxide of iron acting as a binding material. He uses these mixtures either to ram the interior of converters or other iron and steel furnaces, particularly their bottoms, or he makes it into bricks and tuyeres under very great pressure. The bricks he prefers to fire at an intense and prolonged heat. He also uses this mixture when made rather liquid as a cement for calcareous bricks; crude creosote may be substituted for tar when it is readily obtainable. He also uses a mixture of very highly fired hard shunk lime made from the siliceo aluminous magnesian limestones (such as described in a former specification) with crude petroleum or similar cheap oils as a material to use for rammed linings, particularly bottoms and hearths, and also to make bricks of. In all cases when using this mixture of petroleum and highly fired shunk lime he exposes the linings and bricks (after the linings are in position or the bricks made) to a further very intense and prolonged firing. This mixture also may be used as a cement for basic bricks.

SPURIOUS COLORING OF WINE.—Mix together equal parts of diacetate of lead and the wine to be tested, well shake and filter. If the wine be pure the filtrate will be quite clear, but if colored with aniline it will be more or less colored, according to the amount of coloring present. Another method is to add a solution of caustic potash, in sufficient quantity to neutralize the acid. If the wine be pure it will first produce a bright red coloration, then after a short time turn to hottle-green, and then to a brownish green, but no precipitate is formed; but if the wine has been artificially colored the following colorations will be produced:

Wine colored with	Color Produced
Elderberries.....	Purple
Logwood.....	Reddish Purple
Mulberries.....	Purple
Beetroot.....	Red
Litmus.....	Light Violet

A good test for logwood is to evaporate the wine to dryness, and then add hot water with a little alum, which will produce a blue coloration if the wine has been colored, but will have no effect if the wine be pure.—*English Mechanic.*

LUBRICANTS.—The choice of a lubricant is frequently ill-made. Common kerosene oil is too often injudiciously used in place of a thicker or more bland oil, because the heat produced by the friction rapidly vaporizes the oil and leaves the journal dry. Crude petroleum for the same reason is fitted only for very slowly revolving journals, such as water wheels. For very heavy machinery, or for gearing, tallow and black lead rubbed up together is the best lubricant, and is also the best for wagon and carriage axles during the hot weather. For light-running machinery sperm oil is the best; good olive oil, that has not become rancid and acid, is perhaps the second best, and for winter use lard oil is excellent, but is rather too drying to be a first-class lubricant. Castor oil is better for axles in the winter, and black lead with it is a help at any time.

NEW PREPARATION OF CARBOLIC ACID.—Messrs. F. C. Calvert & Co., of New York, have introduced for domestic disinfecting purposes, eoludified disinfecting tablets containing 50% of concentrated carbolic acid. The great advantage of this solid form is that it removes the danger of accidental poisoning, and from the high percentage of acid present, the tablets provide, even when dissolved in a considerable quantity of water, a solution capable of arresting all kinds of putrefactive change, and of destroying all the lower forms of insect, vegetable, or germ life.

DUCTILE ZINC.—In order to remove from plates and other forms of zinc its natural rigidity and consequent fragility, which render it difficult to work and greatly limits the range of its use, Mr. James Eade, of Waltham New Town, proposes to subject it to special treatment. Supposing sheet zinc is the material to be treated he prepares a bath of linseed oil, and into it he plunges the zinc plates, subjecting the same to the action of oil while in a state of ebullition for 30 minutes, more or less, according to the thickness of the metal; he then removes the plates from the bath, and after the oil is drained therefrom he cleans their surfaces, when they will be ready for the market. Plates treated after this manner will be found to possess great ductility, and to be capable of receiving and retaining a high polish; they may be employed in lieu of lead or pewter in a great reduction of cost for a variety of purposes, as, for example, the linings of sinks and cisterns, and the covering of counter and other surfaces requiring a protective metallic covering. It is proposed to treat other articles than plates in a similar manner to that above described to facilitate the working of the same into various forms.

NEW PERCUSSION CAP FOR DYNAMITE.—Parties in Dusseldorf have devised improvements in caps for dynamite, which consist, first, in weakening the bottom of the cap, by a ring or cross; secondly, in closing the cap as firmly as possible at the top, which is effected by placing a conical copper cap within the same, provided with a hole in its bottom; and thirdly, in strengthening the sides of the cap as much as possible. Detonating caps, as is well known, serve to explode dynamite and similar substances by a strong shock and great heat. By concentrating these as much as possible towards the center of the exploding cartridge or blasting hole charge, the latter are rendered the more reliable. The conical copper cap can also be held within the outer cap by narrowing the mouth of the latter. The manner of applying the above-named principles of construction may be varied as desired according to circumstances.

GALVANIC-RELIEF PLATES.—A recent French patent contemplates the embellishment of metallic plates, to be tinned or galvanized, by submitting them, after being suitably polished and grained, and printed upon with the pattern to be shown in a greasy ink, to the action of an acid bath, by which the exposed parts of the plate are bitten in or deepened, and the parts protected by the ink are left in more or less relief as may be desired. The necessary relief having been secured, the plates are removed from the acid bath, the ink removed either with aid of heat or of solvents, and the plates submitted to the galvanizing or tinning bath, or to an electro-plating process, as may be desired.

GOOD INK.—A commission lately appointed by the Prussian government, to investigate the best class of inks to be employed for official use, state that aniline inks are not suited for this purpose, because they can be easily washed away, especially by preparations of chlorine. Inks, in the composition of which alizarine (Adrianople red) is employed, can be obliterated less easily; but they are of opinion that the best of all is made from gall nuts and a salt of iron, the old description of ink.

GOOD HEALTH.

CARE OF THE TEETH.—Rare, indeed, do we find a person of 30 years of age with a sound set of teeth. Far more often do we find young lads and girls of 10 to 16 years of age whose teeth are mere shells of decaying tissue, rotting away with almost visible rapidity, depositories of decaying particles of food, and the source of contaminating elements which deteriorate digestion, and offensive odors which contaminate the breath. In connection with this, it is said that there are 12,000 dentists in the United States, who annually extract 20,000,000 teeth, manufacture and insert 3,000,000 artificial teeth, and consume about three tons of pure gold, to say nothing of the enormous quantity of mercury, tin, silver and other metals used as "fillings" for carious teeth. We have this upon the authority of *Good Words*, and can only add that judging from the vulcanized rubber required for gums and plates, the rubber-tree cultivation must needs be assiduous.

PRIZE FOR ESSAY ON DIPHTHERIA.—The Empress of Germany has offered a prize of 2,000 marks (\$500) for the best essay on diphtheria. The conditions are that the writer is to bring forward important new facts as to the essential nature (*das Wesen*) of the disease, especially with regard to the infectious matter which propagates it, its dissemination, and the means of arresting its progress. The essays may be written in German, English, or French, and must be sent to Prof. v. Langenbeck, Berlin, N. W. 3 Rooststrasse, on or before December 15th, 1880. The committee which will award the prize consists of Professor Klehs of Prague, Liebreich and Virohow of Berlin, von Nageli and Oertel of Munich, and Thiersch of Leipzig. Each essay is to have a motto corresponding to a similar motto on a sealed envelope containing the author's name.

PAINLESS DEATH.—In one of his lectures Prof. Tyndall spoke of the great probability that entire absence of pain accompanied death by lightning. It is popularly supposed that an impression made by the nerves, a blow or puncture is felt at the precise instant it is inflicted, but such is not the fact. The seat of sensation is the brain, and intelligence of the injury must be transmitted to this organ through a certain set of nerves, acting as telegraph wires, before we become conscious of pain. This transmission or telegraphing from the seat of injury to the brain takes time, longer or shorter, according to the distance of the injured part from the brain, and according to the susceptibility of the particular nervous system operated on. Helmholtz, by experiments, determined the velocity of this nervous transmission in the frog to be a little over 55 feet per second, in the whale about 100 feet per second, and in man at an average of 200 feet per second. If, for instance, a whale 50 feet long were wounded in the tail, it would not become conscious of the injury until half a second after the wound had been inflicted. But this is not the only ingredient in the delay. It is believed that in every set of consciousness a determined molecular arrangement of the brain takes place, so that, besides the interval of transmission, a still further time is necessary for the brain to put itself in order or its molecules to take up the motions or positions necessary for the completion of consciousness. Helmholtz considers that one-tenth of a second is required for this purpose. Therefore, in the case of a whale, one second and one-tenth would elapse before an impression made upon its caudal nerves could be responded to by a whale 50 feet long.

NEW PROPERTIES OF CARBOLIC ACID.—The chemistry of carbolic acid has recently become better understood. For instance, Staedler has shown that it is a constant constituent of the urine; Brieger has shown that it is a normal constituent of the contents of the bowels; and Baumann has discovered that it is one of the products of the putrefaction of albumen. Dr. Jay has lately discovered that it is a powerful deoxidizing agent, and shows this property by experiment. He oxidizes Guaiacum resin with potash, manganese, iodine and chlorine, and deoxidizes it as well as restores it to its normal color by the addition of carbolic acid. A very curious reaction is effected by this acid upon iodine. When carbolic acid is added to tincture of iodine no perceptible change takes place, but when carbolic acid is added to tincture of iodine freely diluted with water, the fluid is almost instantly decolorized, and a compound is formed which is incapable of acting on starch and turning it blue, as free iodine does. Whence the Doctor thinks this combination might form a good antiseptic dressing for wounds. The investigations of Pasteur, Tyndall, Sanderson, Lister and others have clearly shown that putrefaction changes never take place without the presence of bacteria; and, further, that the bacteria are dependent on oxygen for their existence. The deoxidizing properties of carbolic acid would prevent the formation of bacteria.

SUMMER AND ITS DISEASES.—This is a bright volume of the *Health Primer* series, published by Lindsay & Blakiston, Philadelphia, and for sale by A. L. Bancroft & Co., S. F. It is, however, more adapted to a variable climate, where "the changing seasons remind man that the seed is not quickened except to die, and each one brings to him, as it comes with its many blessings, some new suffering and sickness." The book aims to point out the causes of summer sickness, and by proper warnings enabling all to avoid those combination of causes which bring about so many death strokes in summer. "Preventive medicine is the highest development of the healing art." We can avoid occasional much more easily than we can combat maladies already established. The series may be considered a "blessing" in literature. Dr. Wilson is the author of this last one, and all stand upon the highest medical and scientific authority.

COAL OIL AS A PAIN-KILLER.—The efficacy of coal oil as a pain-killer is not generally known, nevertheless it has curative properties to a remarkable degree. This was illustrated by an incident which happened at the Talisman mine a few days ago. On Sunday afternoon a man named John Jones was sitting in the hoisting works, when a large black spider, of the venomous species, bit him on the side. It caused great pain, and the resources of the workmen were taxed to suggest means to relieve the sufferer. At length Mr. Green, the engineer, got some coal oil and applied to the affected part, when the pain ceased almost instantly, and no trouble has since been experienced from the bite.—*Amador Ledger.*

BORAX AND NITRATE OF POTASH FOR HOARSENESS.—These two salts have been employed with advantage in cases of hoarseness and aphonia occurring suddenly from the action of cold. The remedy is recommended to singers and orators whose voices suddenly become lost, but which by these means can be recovered almost instantly. A little piece of borax, the size of a pea, is to be dissolved in the mouth ten minutes before singing or speaking; the remedy provokes an abundant secretion of saliva, which moistens the mouth and throat. This local action of the borax should be aided by an equal dose of nitrate of potassium, taken in warm solution before going to bed.—*La France Médicale.*

Saturday Morning, Oct. 18, 1879.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Field of Chemistry; The End of the World; Sierra Mojadas Mines; Inside vs. Outside Amalgamation; Howland's Undercurrent Sluice Rifle, 241. The Week; A Serious Undertaking; Plate Amalgamation; Wasted Gold, 248. An Eastern Mining View; How Mining Should be Conducted; New Metallurgical Works; Ehrenberg, Arizona, 249. The Railroad Commission, 252. Notices of Recent Patents, 253.

ILLUSTRATIONS.—Howland's Undercurrent Sluice Rifle; New Fly-Wheel Pump, 241. View of Ehrenberg, Arizona, 249.

CORRESPONDENCE.—Arizona Mining Districts; Mechanism Shown at Stockton Fair, 242.

MECHANICAL PROGRESS.—Hydrometer Vessel; Electric Drawing Apparatus; Large Crank Shafts; Electricity in the Apary; New Crusher; New Method of Supplying Water, 243.

SCIENTIFIC PROGRESS.—New Pencil as a Substitute for Ink; Books of Olden Time; Discovery in Photography; Improved Telegraph; A Discovery in Guntery; Slag Cement; Effects of Pressure on Various Substances; Silvering Mirrors, 243.

MINING STOCK MARKET.—Sales of the San Francisco, California and Pacific Stock Boards; Notice of Assessments, Meetings and Dividends, 244.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Utah, Montana, Colorado and Washington, 245-252.

USEFUL INFORMATION.—Prussian Blue from Red Oxide of Iron; Refractory Bricks and Furnace Linings; Spurious Coloring of Wine; Lubricants; New Preparation of Carbolic Acid; Ductile Zinc; New Percussion Cap for Dynamite; Galvanic-Relief Plates; Good Talk, 247.

GOOD HEALTH.—Care of the Teeth; Prize for Essay on Diphtheria; Painless Death; New Properties of Carbolic Acid; Summer and Its Diseases; Coal Oil as a Pain-Killer; Borax and Nitrate of Potash for Hoarseness, 247.

MISCELLANEOUS.—Utilizing Blast-Furnace Slag, 242. Carbonate Belt of Colorado; Friction and Lubrication; North Carolina Gold Region; Spontaneous Fracture of Castings; Homer District, Mono Co., 246-247. Bingham Canyon, 252.

NEWS IN BRIEF on page 252 and other pages.

Business Announcements.

Assessment Notice—Orion Mining Company.

The Week.

This week has not been remarkable for any unusual stir in mines proper, if we may except the alleged extremely rich discovery of ore in the Sierra Nevada mine. The sturdy miners and prospectors are making their efforts felt in every direction by bringing to notice profitable claims of gold and silver ore. Mono county mines are appreciably gaining in importance. The hydraulic mining business is assuming huge proportions, as reports indicate preparations on a large scale.

Perhaps the most noticeable event of the week is the alleged discovery of immensely rich ore in the drift on the 2300 level of the Sierra Nevada mine on the Comstock, choice samples of which are said to have assayed from \$1,027.42 to \$1,394.40, while the average of five samples taken across the face of the drift was \$668.20. The ore is chloride and sulphuret, carrying a large proportion of gold.

The Indian troubles in Colorado have been quieted and whatever interference there may have been with mining pursuits in that State has been removed by the settlement of the difficulties with the Utes.

The Land Commission now in session in this city has entered upon a task of great importance, and it is to be hoped that out of the multitude of opinions offered a reasonable medium may be found which will lessen the evils claimed to exist if not entirely cure them.

The first set of hoisting works sent from here to the Black Hills has been shipped by Parke & Lacy to the "Clara and Pierce" mine. It consists of a pair of 10x12 engines, with five-foot reels and cut-gearing. Although the Black Hills country is so much nearer the East than here, our agents and manufacturers do get an order occasionally. Two of the largest mills in the Hills were made in this city.

CASSIAR miners are going to Sitka.

A Serious Undertaking.

The United States Land Commission has now fully entered upon its important task of ascertaining from expert testimony the proper information necessary to bring about a change, or modification in the laws and regulations applicable to our mining and agricultural interests. Its sessions are well attended. There is no difficulty in procuring the opinions and experiences of men who have carefully examined into the causes of this confusion which prevails in regard to these paramount interests of the Pacific States and Territories.

It will not be an easy task to frame laws and regulations which will cover every conceivable question which may arise with reference to land matters, or which the ingenuity of the human mind may suggest for solution. The fact of the existence of this Land Commission appears to demonstrate that the accumulated changing circumstances of different localities, various manners and customs, cannot, except to a certain extent, be governed by any general laws. There are a multitude of intricate questions constantly being presented for settlement, which are all the more important on account of the near approach of apparently conflicting interests. We refer to the claims of miners and farmers. We expect to hear very many conflicting opinions upon the points which may be, and have been already, raised by these two classes of our population, which combined constitute its wealth and greatness. But these opinions will undoubtedly be founded upon years of experience and formed after mature deliberation. Whether any good results will accrue through the Commission can only be hoped. The point to be feared in matters so important to the public welfare, is that too much meddling with existing and tried laws will bring upon us the very evils that people in general are seeking to avoid.

Many defects in existing laws arise from the incompetency of those possessed of the authority of executing them; many claims have been lost through blunders of the parties themselves, or their attorneys, and there has been too much "sticking to the hark," the spirit of the law having been persistently ignored. The law is not measurable for mistakes of misconception or misunderstanding, so we must lay aside the opinion that the law is inadequate, defective and incompetent. To assert it is to utter a parody upon our power of self government.

The changes that are recommended by the witnesses so far, are not of a sweeping character, but refer more to the condition of things in a peculiar locality. For instance, a Comstock thinks the square location with vertical side lines the very best, although it would not do where there is a pitch to the lode, as in the case of the Comstock. An appeal to nature to straighten up all lodes would be in place here, for the witness from a mining region containing lodes seriously afflicted with "dip" declares the square location to be an unjust one, for the locator of a claim or lode ought to be allowed to follow it wherever it goes, within the limit of the end lines. Another witness thinks it would be very unwise to give the subterranean or mineral wealth of the lands to surface owners. We might fill several columns with the various opinions offered and remedies proposed, but there is nothing that has not been repeatedly mentioned in local newspapers or on the rostrum.

Upon the debris question there are no new ideas advanced. The interests of the miner and farmer are distinct, but need not necessarily conflict. The importance of both is so well understood that it seems to be nonsense to argue about it. Whether the debris business will ever be settled to the satisfaction of all the parties is a question which time alone can determine. It is, perhaps, certain that a mere law will not apply a perfect or satisfactory remedy. This seems all the more probable from past experience in laws—constantly changing and seemingly never settling any question like that involved in antagonistic interests. Law is too much regarded as a stern, unyielding principle of justice, a sort of a "break but not bend" affair, and the question of expediency being left out, the American mind is prompted to rebel when his common sense declares that the spirit and not the letter of the law should be maintained.

There are principles of equity in this debris question which no law can, in our opinion, reach. It may be regulated by law, but the principles of equity are too æsthetic to be reached by legislatures; they border upon the conscientious, and over conscience the governing power has no control.

At the bottom of the difficulty lies the doctrine that every man should use his own property so as not to injure the property of another. This doctrine is accepted from an old and well-known maxim, which is frequently urged in courts. But it appears to everybody, and one man cannot in justice urge it in his own behalf, while the fact of his requiring its application to his own particular circumstances and surroundings, would operate as a violation of it applied to the circumstances of others. The same law which says to every man "you shall be protected in your legal rights," also says in its spirit: "If the use of your legal rights operates to the detriment of another, you are violating an equitable principle which

you cannot be compelled to adopt, but which is nevertheless 'good conscience.'" The majority of mankind naturally comprehend the distinction between law and equity, or what may be termed the "governing element" and "good conscience," but do not fully see that there is no affinity; hence the desire to change the law originates mainly in the desire or hope of uniting these two heterogeneous principles between which there is and can be no affinity. Equity is left solely to common sense. We notice in the various opinions offered before the land commission, this undercurrent of desire or hope, which can hardly be realized practically. Hence, we say, the undertaking of the commission is a serious one. It must confine itself to points relating to government, and cannot, although it will be expected to, enter into the domain of equity and enforce the operation of consciences.

Plate Amalgamation.

In selecting a suitable metal for amalgamating plates the most important point to be taken into consideration is its action with quicksilver. All the base metals to which quicksilver adheres at all are more or less soluble in that substance, and in proportion to their solubility are they unfitted for this purpose. Zinc for instance, which readily amalgamates with quicksilver, and at first presents a very fine surface for gold-catching purposes, very soon dissolves to a thick amalgam, and on the addition of more quicksilver becomes liquid, and is of course worthless. For this reason copper has been settled upon as being the least soluble of all the available cheap metals for mill plates, but copper has many and serious objections, and in the long run cannot be considered near as cheap as if it were at first heavily plated with silver or even gold itself, which is admitted by all to be the best agent for bringing quicksilver in contact with fine particles of gold in pulp. It is noticed in mill mortars crushing gold ores that wherever a little stray amalgam finds lodgment it rapidly increases in quantity. As soon as a copper plate is coated with quicksilver, the quicksilver begins to eat into or dissolve the copper and the particles thus liberated float to the surface, where coming in contact with air or other salifying agents, produce that extremely annoying film known as "verdigris," and so prevent the contact of gold and quicksilver necessary to amalgamation. This action or solution, though extremely slow, is sure and certain, and continues as long as the two metals are exposed to direct contact. The coating of mercury on a copper plate, though usually very thin, always has an appreciable depth, sufficient at any rate to permit of the movement and arrangement by gravity of particles held in suspension therein, and as the copper is slowly dissolved away the place of its atoms is immediately filled with others of denser gold amalgam, and the form of the plate is thus preserved, though in substance it is gradually changing from copper to gold amalgam.

This process is, of course, more rapid in the beginning, when the mercury has free access to the copper than it is later on after more or less gold has intervened between the two metals, and it gradually diminishes until the "verdigris" or oxide of copper only rises in such small quantities that it is ground off by the action of the running pulp on plates in active use as fast as it forms, and not until plates reach this condition are they presumed to be in good shape for gold saving. But the fact that the verdigris continues to rise in small quantities may easily be proven, for if we take one of these plates, no matter how old, so long as there is copper left in it at all, and place it under conditions which will allow the copper to oxidize (and we can hardly place it under other) we will find that in time a green film will form on the surface of the mercury. Now a plate that is sending up verdigris, even in the smallest quantities, is not as good as one that does not, and therefore a copper plate never does become the equal of a gold one, and is never considered in prime condition until it has actually accumulated and secreted more than enough gold to form a plating sufficiently heavy to insure insulation of the quicksilver from the copper, even in case of the rather severe scraping with steel tools to which it may be subjected. It cannot be doubted that the gold so accumulated could be much better applied as a plating, for it would then present a smooth, solid and even surface, and practically invulnerable to the inroads of the quicksilver, whereas by the present method it is slowly deposited as a hard amalgam, which eventually renders the plates so brittle that they become fit only for the fire.

The fact that a new or "green" copper plate absorbs gold much faster than an old one, serves in a limited measure to explain the very common disappointments attending experiments with them, and that the first clean-up in new mills usually falls short of expectations.

Although copper plates, heavily plated with gold would certainly be much cheaper, cleaner and more effective than raw copper, we do not know of their having been adopted in any instance, though there is a growing demand for silver plated which appear to give general satisfaction and to be an acknowledged improvement. Although silver is practically non-oxidizing under ordinary circumstances and nearly as insoluble in mercury as gold itself, time may develop defects as yet unseen.

Wasted Gold.

The amount of gold heretofore wasted by ancient manipulations, if twenty or thirty years ago may be termed ancient, is almost incredible. It is a fact, however, which miners have for several years realized, that there is an immense field for productive mining in merely working over refuse and tailings, and collecting the gold which has been wasted. Indeed there is hardly a doubt that it will pay better than some original workings, considering the lowness of this expense. Upon this subject the *Amador Dispatch* says: "Recent assays of the old heap of refuse matter at the Good Hope mine near Jackson, showed from \$15 to \$30 per ton in gold. This matter was not considered worth milling, in fact would not pay the hauling and milling expenses."

Again, in Plumas county, at Chaparral hill, the old-time mining camp known as Mount Pleasant contains untold wealth. Thousands of dollars have been cleaned up in the old worked-over placers, and Chinsmen are still working them over. Crossing the ridge to the old Fales Hill claims we find that the latter are 85 feet lower than the hedrock cleaned off at the Mountain House, and that there is one mile of channel which has never been touched, being probably 500 feet deep of wash gravel and quartz from surface to hedrock. Every miner who ever worked there has been of the opinion that buried there is enough of the shining dust to make capital for an army of men, but this ground although claimed frequently has always been abandoned, and so far no work has been done to develop the enormous channel. The two rims show that it must be more than a quarter of a mile wide, and on the north, or Feather river side, some very large springs break out and flow down towards the river.

The mines of Tuolumne county are yielding more gold at the present time than in early days, proportionate, of course, to the number of workers. Gold seekers are now less by thousands, but the production of gold has by no means decreased in the same ratio. Continuing in this strain the *Tuolumne Independent* remarks that: "The mines worked to-day are of a more permanent nature, and increase in value as they are more fully developed. Placer mining, from its very nature, was of brief existence, and in many instances, doubtless, destroyed more ground for future usefulness than all the gold taken out would pay for many times told. In fact, as a mining section, we believe the county has hardly yet been prospected. It is only in spots that we have an indication of the rich stores buried deep beneath the surface; how deep no one has knowledge. The thousands of acres yet untouched for mineral, except by scratching on the surface, is doubtless laced beneath with veins of gold-bearing quartz; and the gravel beds of many miles in extent and unknown depth, have as yet remained unexplored by the little giants so busy in other sections of the State. The immense deposits of gold in the ancient river beds under Table mountain, running through the county, have also remained undisturbed except at one or two points, which but sampled the value of the miles of golden channels yet covered by the debris of centuries. Tuolumne, as a mining county, is yet in its infancy, not dreaming, even, of the wealth future years will reveal."

There is hardly a gold producing county in the State that does not contain vast resources of undeveloped wealth, either in old refuse or in undeveloped continuations of old mines, which may truly be termed "wasted gold." Upon the point of our resources the *Grass Valley Union* truthfully says: "For hundreds of miles along the western base of the Sierras are gold-bearing veins and placers awaiting development that will yield a profitable return to the energy and money of the capitalists who will yet seek this field as one of the best and most reliable to be found on the globe. Here will be found every facility of a kindly climate, accessibility, cheap and available power, and every concomitant that can make the business profitable above the cost of production. The gold mines of California, notwithstanding the vast treasures they have given to the world, are comparatively unworked fields. The gold-bearing veins are practically without limit, and the dead river channels are only beginning to yield their inexhaustible stores. This is not an overdrawn estimate of the gold fields of California, and far-seeing men are beginning to realize the importance of giving more attention to them as a source that will be lasting and reliable in keeping up an equitable production of the metal that is pre-eminently the need wherever the wheels of industry are in motion or commerce spreads its sails."

HALF-RATE NIGHT TELEGRAMS.—We are informed by the Manager, F. Drake, Esq., that on and after the 1st of November next the Western Union Telegraph Co. will transmit messages offered any time during the day or evening, but sent after all other business is clear at night, and deliver the same next morning, at one-half commercial rates, the tolls in no case to amount to less than 25 cents. Messages will be received under this arrangement for any Western Union office in the United States.

The value of the exports for the last quarter from Victoria, B. C., aggregate \$817,134.

An Eastern Mining View.

Judging from an article upon Colorado as a mining country in a recent issue of the New York Mail, Colorado is exciting the Eastern mind more by reason of its mineral wealth than its Indian troubles. It says: From this present and daily increasing indications, it is obvious that the bullion output from Colorado, before long, will equal, if it does not exceed, that of any other State or Territory in the Union. The vast and continuous mineral belts continuing from Boulder county to San Juan point, in our humble opinion, to the slopes of the main ridges of the Rocky mountains, as the future big bonanzas which will, at no very distant day, far surpass in yield anything yet produced in California or Nevada. All geological theory points incontrovertibly to such a conclusion. We are not disposed to be hypercritical so far as the success of any of our neighboring States and Territories is concerned in any department of wealth-producing material. On the contrary we feel that the success and welfare of all or any contributors to a common advantage. It is not necessary, however, to establish an incontrovertible fact upon a geological theory. A conclusion founded upon such a basis is apt to occasion a fear of lost prestige on the part of the rest of the Rocky mountain region.

The Mail feels the lack of adequate smelting and refining works, and thinks a branch mint should be added, inquiring upon what intelligible grounds mints should be kept up at New Orleans and Dahlonega so far removed from any metal-producing centers? As to the smelting and refining works there can be no question that when those actively engaged in mining find it profitable to erect them, or when the output will justify the expense, there will be no lack of machinery and works. So far as the mint is concerned, there are very good ones at San Francisco and Carson City, and the establishing of others to turn out more tons of silver coin to be used as storing material in the vaults thereof, might not be a truly profitable investment for the government. Of course, if there arises a necessity, the Mail need not fear that the want will not be supplied.

One of our late exchanges complained of the damage done to the mining interests of Colorado by Eastern investors, who have a custom of buying mines, putting up extensive works and improved machinery for the purpose of turning out bullion, and when everything else is ready, the mine is examined and found not productive, obliging the abandonment of the works and the loss of much capital. Such a *fiasco* is not uncommon, because the old saying, "All is not gold that glitters," is apt to be overlooked in the highly colored local accounts of mines, and the fact that a mine may have very little pay ore in it, disregarded. The doctrine of "Caveat emptor" applies to the purchase of a mine as much as it does to that of a horse. We make these remarks in the hope of putting the Mail on its guard against erecting smelters and mints without necessity. Colorado is an immense country. Indeed, all and every one of our Rocky Mountain States and Territories are too immense to be generalized. Carbonates and chlorides and tellurides are not found everywhere, however, but they exist in well-known and well-defined localities, and though very rich, yet when a whole State or Territory is spoken of as the universal depository of the precious metals it is indeed a geological theory. The Mail declares that "the best developed fissure veins of Colorado are little better than insignificant holes in the ground compared with the solid engineering work in mining which exists in Nevada, where a depth of 2,400 feet has been reached in shafting, and everything connected with the work done on a scale and in a manner unequalled in the world. An opinion that we have heard frequently confirmed by European engineers who have visited Nevada and expressed their great surprise and admiration at finding scientifically planned and skillfully executed work extended to perfection, where they expected to find little beyond the most ordinary and temporary work. Above all stands the Sutro tunnel as one of the grandest works of any age, bold and admirable in plan, and no less admirable in execution, a work whose effects on the rich ore beds for so long flooded and unproductive will, unless all well-defined theories and actual experiences are utterly at fault, develop an output of the precious metals which will fully repay the labor and money expended on it," but comes back again to the uppermost thought in its mind, engendered possibly by reading up "Little Pittsburgh," and says that "Colorado, too, is already having her tunnels, though, of course, not on a scale that will at all compare with the Sutro." This frank statement relieves our fears of being surpassed, and brings Colorado to the level of all our other gold and silver-producing States, where it must remain, and every effort to magnify it or any other State or Territory into a vast bonanza, geologically constructed to astonish the world by its extraordinary output of precious metals, will only bring a bad return in the shape of lost fortunes and disappointed hopes. The geological facts

are that the whole Pacific coast region is rich in precious metals, and not only does not show any signs of exhaustion, but is showing continual new and rich discoveries. With us, in this State, mining is not continually alluded to because other and valuable interests have been conjoined. Our interests as regards the precious metals have developed into a steadier and quieter business than in now mining regions where, in the fever of excitement, every strike of any portent is made a bonanza that will cast the rest of the world in this shade. Because some of our capitalists invest in outside mines is not a reason for exaggerating the resources of any region. Capitalists may possibly make more money by speculating in mines, as a real estate agent would in corner lots, hold them for a rise, for instance, than in actually working them. Such things have happened, and are likely to continue. Again because our capitalists have largely invested and are working rich mines in Colorado, let no man infer that there are plenty other mines equally as rich. The best locations have undoubtedly been selected, and the California capitalist is not the one to let valuable new ones get far away from his reach.

How Mining Should be Conducted.

Legitimate mining should be conducted with the same rigid economy that renders mercantile transactions more liable to be successful. The merchant studies closely the cost of his merchandise, examines and scrutinizes its quality, and places a fair profit upon it when offering it to a purchaser. If he deviates from these principles, a failure will be the termination of his operation. When mining is brought under the influence of these principles, its success may be safely assured. The merchant studies the cost

think we have set forth the leading causes that have produced such results.

The preventive course against the continuance of the evil is for the prospector and subsequent workers of a location to be cautious and cool in their preliminary examinations. Look well to the character of the adjacent ground. Study carefully the indications which the lode presents. Ascertain if the rock is truly metalliferous or merely spotted with ore. Attention should be given to the availability of timber and surface water; to the accessibility of the mine to water communication, railroad, or common transportation; and to the possibility of decreasing the cost of getting the working materials to the mine, and getting its products to the great centers of trade.

A close and accurate account should be kept of all expenditures, which, if classified into the various departments of the work on the mine, would be still better; and also of the yield of the mine. It would be a simple matter to strike the balance, and ascertain if the adventure was profitable or not. It would give an opportunity by referring back to these items occasionally to find where some portion of the expense might be avoided in the future by more judicious purchases, or by not buying again similar articles which were not actually requisite.

Efficient and capable superintendents should be employed. They should be men who have had experience in working mines, who possess the executive ability to manage the men in their employ, and the mining knowledge needed to solve practically the difficulties that so frequently confront the man in their labors. They should be cool and brave on all occasions, for the lives of the men might be jeopardized were they not so, or the loss of a shaft, tunnel or level might entail a heavy expense, from heated or precipitate action on their part. The men should be governed firmly, without harshness,

New Metallurgical Works.

A want has long been felt in this city for some place where working tests of ore could be made by any desired process. People frequently want small batches of ore practically worked in this way it is to be on a large scale, but there has been no place to do this where all the various appliances were provided. Messrs. Kustel & Riotta have now, however, established metallurgical works at No. 318 Pine street, where ores are crushed and sampled, and working tests made by any process. Assaying and analysis in all its branches is practiced, and metallurgy of gold and silver taught theoretically and practically.

At this place the necessary mill process can be exactly carried out. There is first a little Blake rock crusher for breaking the rock, and one of Kendall's ore stamp mills for crushing it. This little stamp works admirably, and as any size screen can be used, the work of a large mill can be done on a small scale. In front of it are the amalgamating plates and sluices, and there are also pans and settlers for use in connection with this mill. A wooden pan is also provided, and the ore may be crushed, wet or dry.

Leaching tubs and vats are arranged for chlorination or lixiviation processes, with all the necessary appliances. They have a roasting furnace, a smelting furnace, assay and cupelling furnace, a refining furnace, and all the manipulation of ores requiring fire may be tried. There are also ore scales, assay and bullion balances, a complete chemical laboratory, retorts of different sizes, arrangements for testing small samples of ore by pan or horn spoon, and, in short, all the appliances for testing or working ore in any desirable manner, and on a scale which furnishes a complete practical working test for any kind of ore. The furnaces are all arranged so that the fumes are carried away readily. In the rear is a large sampling floor where the process of sampling ores may be carried on. If desired, any of the processes may be carried on in the presence of the interested parties. Tests for the proper process for any ore may be made with facility when all the various appliances are so ready at hand.

Mr. Guido Kustel is a miner and metallurgist of life-long experience, and has been on the coast for 25 years engaged in business connected with the mining interests. He is the author of several well known mining works and has had large experience with the various processes. Mr. E. N. Riotta has also been engaged for many years in mining pursuits, and bears an equally good reputation as an expert assayer and metallurgist. Mr. H. Kustel has been associated with his father for several years in the same class of business. These gentlemen are practical men, thoroughly conversant with the various processes for treating ores, and competent to undertake any sort of work in this line. With so complete an establishment as they now have in every respect, miners may have batches of ore properly worked by any process and rely upon the results as being correct.

Ehrenberg, Arizona.

We offer our readers on this page a cut of the town of Ehrenberg, Arizona, taken from the Continent Stereoscopic Company's work, "Picturesque Arizona." The view looks up the Colorado river, on the left, the California side, covered with a dense cluster of willows, grease-wood and small timber. At the time the drawing was made the town of Ehrenberg was a unique settlement, composed mainly of Mexican or Indian huts, but has undoubtedly improved its appearance since 1877. The soil is very fertile, and must attract the attention of those interested in the development of the country through its agricultural features. It is difficult to conceive a correct idea of Arizona as a whole, so vast its extent, so varied its resources, and so wonderful its features, that the mind naturally selects some single attractive feature to the exclusion of all the rest. The contrasts of the Territory are immensely striking, and beget a beauty, the interest in which grows constantly.

For general and prolific productiveness the more southerly portions of Arizona probably excel; the wonderful must be accredited to the northern part, while along that peculiar river, the Colorado, the charm of mystery hangs like a cloud, which Indian traditions have generated, and it seems a pity to dispel it by the light of modern development.

SUBTERRANEAN EBB AND FLOW.—There are coal mines in Germany in which the phenomenon of subterranean waters having a regular ebb and flow has been observed. The scientific academies of Vienna and Berlin are studying it, and look for valuable additions to our knowledge of the earth's interior.

VIEW OF EHRENBURG, ARIZONA.—INDIANS AT PLAY.

of his merchandise. The miner certainly should do so also, whether the cost consists in the price he pays for a mine, or in the expense attendant upon working it. If he pays an exorbitant price for the property, too much for the labor expended in its development, too high a price for the material used in prosecuting the work, he will soon learn by sad experience that by deviating from strict economy he has brought about his own ruin.

A disrepute has been cast upon mining by the reckless and careless manner in which investments have been made in mines. Instead of a rigid examination as to the quantity and richness of the ores, extent and probable durability of the vein, under the impulse of a wild, speculative disposition, injudicious outlays have been made, and properties purchased or explorations instituted, where, under a careful scrutiny, not a dollar would have been expended. If any mining district is visited, the surface of a great portion of it will bear evidence of the truth of the above assertion.

If the merchant pays too much for his goods, he can get back in their sale a portion of his money, for they possess a tangible value. If the miner sinks useless shafts and prosecutes useless labor, the loss is total to him, for there is nothing in its results that can by any possibility be rendered available. Our mining camps are full of actual texts of this description, each one of which is a visible sermon for the benefit of the observing miner, if he will only profit by the instruction which it is their province to exhibit.

No man works harder than the miner; no man strives more earnestly to obtain profitable results from his labors than does the miner; no man undergoes more privations than the miner; and no class of men meet with such general and continuous failures as the mining men. In the general rule, those among them who are successful are not so from the exercise of caution and scrutiny, but simply because they have blundered or stumbled upon fortunate locations. With failures being the rule and success the exception, there certainly must be an underlying cause for such an untoward condition. We

resolutely but kindly, and with a due regard to equity. They should be made to faithfully perform the work before them, and should be promptly paid at stated times the full amount of their wages then due.

As was stated at the commencement of this article, mining should be conducted upon strictly business principles, to ensure success. When the mines on this coast are managed in accordance with these principles, we will see the mining interests assuming their proper sphere, and mining itself be elevated above the great uncertainty that now surrounds it. Then a justly confiding public will sustain and support mining operations, and investments in them will be considered as wisely made and as safe as those which appertain to other channels of industry.

S. P. L.

A SINGLE TRACK RAILWAY.—A movement is now on foot to give a practical test of the James single track railway system, by building a mile of road back of Antioch, Contra Costa county. The money has been subscribed to defray the expenses of the experimental trials, and a meeting will be held within a few days at Antioch to determine the precise locality for building the mile. The locomotive drawings of which we have seen, will, in all probability, be built by the Union Iron Works in this city. An engine of a capacity of hauling 300 tons can, it is estimated, be built for a little over \$2,000. It is also estimated that freight can be carried from Mussel Slough to Antioch, a distance of 180 miles, for \$2.50 per ton, whereas it now costs more than \$6. It is thought the cost of building the road will not exceed \$1,200 per mile. If the experimental trials are satisfactory, efforts will be made to construct the road down through the valley to Mussel Slough. Active efforts are now being made to carry the project through.

In New York, Government bonds are quoted at 102½ for 4s of 1907; 103½ for 5s of 1881; 105½ for 4½s; sterling, \$4.82@4.84; silver bars, 113; silver coin, ½@1 discount.

DEWEY & CO'S SCIENTIFIC PRESS Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free. Address.

DEWEY & CO.,
202 Sansome St., N. E. Cor. Pine,
San Francisco.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.
Office, No. 320 Sansome street, Room 10.

GOLD MINE WANTED.

One now paying more than expenses. Address
W. S. KEYES, M. E.,

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

F. MOORECROFT, Stone Seal Engraver.

THURLOW BLOCK,
Room 33, 126 Kearny St., Cor. Sutter, San Francisco.
Coats of Arms, Crests, Monograms and Masonic Inscriptions Carefully Engraved.

LAND Good land that will raise a crop every year. Over 14,000 acres for sale in lots to suit. Climate healthy. No drouths, bad floods, nor malaria. Wood and water convenient. U. S. Title, perfect. Send stamp for illustrated circular, to EDWARD FRISBIE, Proprietor of Reading Ranch, Anderson, Shasta County, Cal.

LEA AND PERRINS' SAUCE,

In consequence of spurious imitations of
which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.
Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

Howland's Under-current, Mill and Sluice Riffle.

This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from flouing or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

AN ENGINEER,

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office.

PHOSPHATE SOAP

THE BEST soap for toilet use ever manufactured. BEST because it contains all the excellencies of the most expensive foreign or American soaps without their defects. BEST because it combines strength with delicacy in such a way that its strong detergent qualities do not injure the skin. BEST because it is the result of years of study and experiment in the soap manufacturing business, assisted by modern chemical discoveries. BEST because it contains ingredients beneficial to the skin, which unite chemically with the soap in such a manner as to increase its saponaceous qualities. Every chemist familiar with soap manufacture knows that some ingredients which are in themselves beneficial to the skin cannot be saponified; some are partially neutralized, while others injure the quality of the soap. There are soaps in the market which are to some extent beneficial to the skin, but they are inferior articles for toilet use. PHOSPHATE SOAP is the ONLY article offered to the public which combines all the best elements of toilet soap with medical ingredients beneficial to the skin.

If your wife is in the habit of using cosmetics of any kind, advise her to give up the pernicious practice, as the most harmless face powders obstruct the pores of the skin and sooner or later injure the complexion, while PHOSPHATE SOAP removes all impurities and assists nature in developing a natural, healthy and beautiful skin.

It is an old proverb that an ounce of preventive is better than a pound of cure. Twenty-five cents invested in a cake of PHOSPHATE SOAP will save hundreds of dollars in doctors' bills. It acts as a constant disinfectant, preventing Salt Rheum and other skin diseases.

If your wife will persist in the use of cosmetics, buy her a cake of PHOSPHATE SOAP and tell her to use it every night before retiring. In that way much of the harm will be avoided, as the skin will thereby be able to retain much of its natural vigor and beauty.

No salve or ointment can heal a wound or sore of any kind. Every educated physician will tell you that nature alone can do this. PHOSPHATE SOAP, by its cleansing, soothing and purifying qualities, gives nature a chance to act freely.

Natural beauty surpasses anything which can be imparted by artificial means. PHOSPHATE SOAP gives health to the skin simply by removing impurities and eradicating the poisons which give rise to skin diseases.

Not only for daily use on the face and hands, but for bathing the entire body, there is nothing equal to PHOSPHATE SOAP. It is a thorough disinfectant and removes offensive odors of every kind.

Ladies who have injured the skin by the constant use of cosmetics may do much to restore their faces to that beauty which nature alone can give by constantly using PHOSPHATE SOAP.

For all diseases of the skin use PHOSPHATE SOAP. There is nothing like it for removing impurities and giving the skin a healthy and natural vigor.

Cheap toilet soaps manufactured from rancid and refuse grease injure the skin and are really more expensive than PHOSPHATE SOAP, which retails for 25 cents per cake.

Thousands of articles are palmed off on the public which have no genuine merit, but PHOSPHATE SOAP is the result of modern discoveries of celebrated chemists.

PHOSPHATE SOAP costs no more than other good toilet soaps, while its medicinal qualities make it worth ten times its price to every man, woman and child.

If you want a nice article of Toilet Soap and something that is beneficial to the skin, buy PHOSPHATE SOAP.

Single samples will be mailed from this office for 50 cents, postpaid. Wholesale and retail agents wanted.

THE BEST FILEHOLDER.—After having used Dewey's patent elastic hinge fileholder for over a year past, the *News* cheerfully indorses it as the best newspaper fileholder in existence, possessing important advantages over any and all others in use. The holders are neat, light and convenient, and the newspapers are placed in them with the utmost facility and least possible time and exertion. They are the simplest, handiest and cheapest of all. Anybody keeping files of papers in reading rooms, offices or at home, should send at once to the proprietor, A. T. Dewey, San Francisco, and get the only proper fileholder. Samples by mail fifty cents.—*Gold Hill News*.

**MINERS' HORSE-POWER.**

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to head-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

[CONTINUED FROM PAGE 245.]

Boston, Massachusetts, interested in some of the claims and they have advanced the capital to work them.

PIOCHE DISTRICT.

RAYMOND & ELI.—*Record*, Oct. 11: H. Mill, Supt., in his report of Oct. 10, says: We are sinking on the 10th in a big body of ore; ledge looks well and is from 8 to 10 ft wide, and everything indicates an enlargement of the ore-body. The 11th is still holding out and next month we expect to take out a good deal of ore. The west drift on 11th still in good ore and prospects are we will have big body. We sent to mill this week 170 tons of ore. General prospect of mine looks well.

TEM PAHUTE DISTRICT.

INCA MINE.—A Chicago party says: A shaft has been sunk 350 ft., and valuable ore taken out. The ledge is from 4 to 5 ft in width, and the ore, according to the reports of reliable experts, will average from \$250 to \$300 per ton in silver. Some of the ore specimens will assay as high as \$12,000 per ton. Shipments of ore have been made to the Reville mill, a distance of 65 miles from the Inca, which have turned out as follows: First grade ore, \$750 to the ton; second-class, \$425 per ton, and third class, \$270 per ton. Cost of working ore is estimated at \$12 per ton.

REVELLE DISTRICT.

GLA MINE.—*Tyho Sun*, Oct. 11: Letter of the 29th says: During the past week the south drift from south drift vein No. 2 was driven 4 ft. In it we have struck a wide vein of good ore and one that promises to yield a large quantity. An average assay of the vein has not yet been made, but the assay of \$336 per ton has been had from a selected piece. The slope in south drift vein is looking well and yielding about 6 tons per day. At the mill we now have 130 tons of ore. It is proposed to start a drift on the 200 level, and strike the continuation of the old ore body worked in 1875, which is probably within 100 ft.

ARIZONA.

PIMA COUNTY.—*The Territorial Expositor* says: A private letter received from Tombstone, Pima county, gives good news from that camp. The mines are turning out large quantities of silver bullion, and all interested in the new town of Tombstone are confident that it will be a large, permanent and prosperous place. Mr. Larry, who went to Tombstone from this place several weeks ago, purchased two lots for \$300, and in a few hours afterwards could have sold them for \$1,200. Forty houses are being built in course of construction, and many more buildings would be commenced were it possible to procure lumber. At present the labor market is overdone, and there are hundreds of unemployed men in the district.

TRUMPS.—*Prescott Arizona*: Mr. G. Poirier informs us that the miners working the assessment of Messrs. Moeller & Rush, in Big Bug district, uncovered a new ledge, two and one-half ft wide, which gives assays in silver, per ton, as follows: Green ore, \$1,162.44; red, \$2.85; black, \$3. We learn that Capt. James A. Moore struck an ore vein of 40 ft in the Globe district, after running a tunnel 430 ft, at a cost of \$15,000. Samples of all grades of rock, divided into three classes, assayed as follows, per ton: Lot No. 1, 690 ounces; lot No. 2, 473 35-100 ounces; lot No. 3, 53 46-100 ounces.

COLORADO.

BIG HORN.—*Telegram from Fort McKinney* says: Great excitement prevails in this vicinity, on account of recent rich discoveries of gold-bearing quartz in Big Horn mountains, about 75 miles northwest of this post, at the head of Tongue river. Large numbers of miners are passing through this place en route to the mines. Nearly all the citizens of this section are leaving for the mountains. One has been assayed with the following results: Lowest, \$41; highest, \$70 per ton.

BOULDER COUNTY.—*The News and Courier* has seen a mill run with ore from the Poor Man's Relief mine which showed net returns of \$602.12 gold and \$37.92 silver per ton. The Grand Central, adjoining the Atom mine, disposed of a mill run on 442 pounds for \$144.07. Another shipment of 133 pounds yielded \$317.47 net. These two mines are four miles from Boulder in the Gold Cliff camp.

PARK COUNTY.—*The Fairplay Tribune* notes a new mining locality at Montgomery. The vein is a very strong and well defined one. Two ft of the vein matter contains a large amount of copper, and an average assay of this two ft yields one and seven-tenths of gold and eight ounces of silver. A body of white iron forms the balance of the vein matter. It runs an ounce in gold and several ounces in silver. A late assay of ore from the Truman mine, on Mount Truman, shows a coin value of \$4,000 per ton, and a ton of mineral on the dump awaiting shipment. Some ore from the Bouanza King extension contained upward of 30% of nickel, besides \$90 to the ton in gold and silver. A new discovery made by Robert Lampkin, on Buckskin gulch, shows a fine body of mineral. The quantity of black sulphurets which this ore carries makes it a high-grade mineral. One sack which was tested last night, mill run, the rate of 200 ounces to the ton. Beautiful specimens of native silver were taken from the crevice, which led to the report published in the *Denver Tribune*, that there was a three-inch vein of metallic silver.

MONTANA.

NEW QUARTZ LODGE.—*The Butte Miner* says: Messrs. W. L. Lee, Morgan Davis and R. K. Emerson, who discovered gold-bearing quartz in the foothills, on the southeast side of the Park, at a distance of about eight miles from this city, have sunk a shaft 20 ft deep, and taken out about 20 tons of ore. They commenced working an arastra on Monday last, by horse power. The first clean-up will take place on Wednesday. An assay made a short time ago, showed \$49.60 to the ton. The operators say the prospect becomes better as they go down.

MADISON COUNTY.—Parties from the Potosi district bring information of the erection of arastras and the opening of new roads in that district. There are some very promising lodes; and a Mr. Hathaway brought in some ore from the Birdseye and Carrie Hathaway No. 2 lode, which was assayed by Assayer S. B. Rice, and found to assay 304 ounces per ton for the Birdseye rock, and 1,052 ounces per ton for that from the Carrie Hathaway No. 2. It is his intention to take a quantity of the latter ore to the Butte smelter, as soon as he can get it out—which will be in a few days.

BUTTE.—A writer in the *Idaho Statesman* says: The operators in the Alice mine expect to strike rich silver-bearing quartz in a few days. It is the same vein that has already been worked. The extension of the shaft is now to about 500 ft, and the workmen are drifting towards the vein. Experts say this camp is destined to become one of the most lively and richest in the world. Z. L. White, of the *New York Tribune*, has been thoroughly investigating as to the outlook, and progressing operations, and says Butte seems to be richer in silver than the Black Hills are. He thinks that this is destined to become a great camp.

UTAH.

BINGHAM MINES.—A correspondent of the *Salt Lake Tribune* says: Each day that passes brings intelligence of some new discovery being made in the gold line, which brings forth the oft-repeated opinion among our miners, that Bingham, as a gold-producing camp, is only in her infancy. The different theories that have been advanced regarding the placer mines of this place are fast becoming exploded. As gold mines in Carr Fork, gold mines in Highland, and gold mines in Bear Gulch demonstrate to a certainty, that the action of the weather on the exposed body of quartz caused decomposition to free the shining metal from the molten rock, and when thus freed was carried by the water and deposited in the canyon below, hence the auriferous gravel formed. Among the latest gold discoveries is the one made in the recent development of the Skagit mine. One pan of rock crushed in a mortar was tried, and \$1.25 was found to be the result of the experiment.

WASHINGTON.

SKAGIT MINES.—By telegraph, from Seattle, we learn that N. E. Goodell arrived there October 8th, bringing eighteen ounces of coarse drift gold from the Skagit

mines. He states that there are now thirty men in the diggings on Ruby creek, who recently struck it rich, and are taking out from \$5 to \$12 per day to the man. The mines were discovered last fall by a prospector named Rawley, who took \$70 in drift gold from a pocket on Ruby creek in a few hours. The news reaching this city and other Sound ports, a rush set in for the mines. Taking it for granted that gold existed in paying quantities in the bed of the creek, some sixty men have been at work all summer constructing ditches for the purpose of draining it. The bedrock, however, was found smooth and clean, with no traces of gold upon its surface. Disgusted with the summer's work, the men began to pack up and leave for home. On their way out, about two weeks ago, a remnant of the force, some 30 in number, camped on the forks of the creek over night, six miles below the scene of their summer's work. Upon leaving next morning, traces of gold were discovered along the banks of the stream. Upon the indication of the men, they went to work, and sent out over an ounce of gold. Since then, the party have taken out some 35 ounces, although a considerable portion of the force have been engaged during the time in packing in provisions a distance of 35 miles, and not engaged in actual digging. Flattering prospects have since been found at several points along Ruby and Canyon creeks.

Bingham Canyon, Utah.

S. R. Dickson, writing from Bingham, Utah, to a late number of the *Salt Lake Tribune*, says that since lead has advanced in price, new life has been infused into the above mining camp. The old mines are being carefully examined and new ones located, in search of emulating ores, or for ores which contain lead, 15% and upwards, in combination with gold and silver. With three or four exceptions, this quality of ore is mined by individuals, most of whom are much limited in means and generally work-leased property. Consequently the output of mineral is limited and uncertain. In the early history of this district, all mining operations were conducted with the single reference of obtaining ores of this description; and ore containing as high as 40 ounces of silver and \$5 in gold, if deficient in lead, were either thrown over the dump with the waste or left in the mine. This anomalous condition in mining is the result of circumstances in which this camp is now and has always been placid. The only means which were then and are now adopted for the reduction of the ores produced, are the smelting furnaces and they are situated upon the Jordan river, about 16 to 18 miles from the mines. The excessive charges for transportation and cost of reduction, made the mining of all ores, containing less than 30% of lead and 15 ounces of silver unprofitable; and at this day, ores of this grade must be free from sulphur to find purchasers for them.

Within the last two years large developments have been made of ore free of lead, but containing gold and silver in a free state, and in such quantities as to make the business of their mining and reduction a source of great profit. The gold and silver of these ores are in combination with iron, which originally was pyrites, but by the action of air and water, the iron has been deprived of its sulphur, and by the absorption of oxygen has been converted into a per-oxide of soft hematite, thus leaving the gold and silver in a chemical condition suitable for amalgamation and cheap milling.

This ore is found in large veins, or, perhaps (in some cases) more properly speaking, deposits, varying in thickness from three to thirty feet, of ore proper, free from gangue and can, in most cases, be mined and milled for less than \$2.50 per ton, and as there exists no question as to the extent and permanence of the mineral veins, the formations being well defined and regular, exhibiting no indications of such disturbance as is likely to produce slips and dislocations of the vein matter, and as the mineral lodes generally conform to the rock stratification, the conclusions are strong that the mineral veins will extend to a great depth, and that their quality and quantity will proportionately improve; neither is there any indication that in this district the miner will experience an increase of temperature as the mines are worked down, such as is founded in the Comstock, the geology of the country not justifying such apprehensions.

The mineral character of the veins is properly described, as first, silver veins, which upon their surface, or outcrop, carry lead, silver and gold, and are worked for smelting ore, the lead disappearing a few feet below the surface, but the gold and silver associated with iron continuing downwards, where the ore becomes a milling or amalgamating ore. Second, an ore which from the surface contains gold and silver in such a state of combination with iron, as to render its reduction by amalgamation less expensive than any other known process; hence such ores are called gold ores.

Many of the old mines, formerly worked for smelting ores, and of such apparently exhausted, are found to be valuable for the milling ore which they contain, and there exist strong indications that many of these old mines, when carefully prospected, will be found of much greater value, for the production of this quality of ore, than they have ever been for the production of smelting ores.

The value of the milling ores ranges from \$10 to \$150 per ton, the lower grade consisting almost wholly of gold, while the higher may properly be called silver ore containing gold, but the relative value of milling ore is by no means dependent wholly upon the amount of gold and silver which they contain. There are many contingencies which so qualify mining and milling operations that it is not unfrequently we see a low grade ore worked with profit, while work upon high grade ores are found financially disastrous. The value of the milling ores of Bingham consists in the magnitude of the veins and deposits and the cheapness with which they can be mined and milled.

The Railroad Commission.

Many people are now waiting with anxiety, and many more with deep interest, to see what will be the effect of the work of the Railroad Commission elected under the new Constitution. It is a matter which will have a marked influence upon our producing interests, and upon wisa and just action on the part of the commission will measurably depend the degree of prosperity which certain regions of our State will attain. While we are thus waiting it is well to expect that the commission will wisely and honestly discharge the high trust placed in it, and it is well also to borrow such assurance as seems warranted by the experience of other countries which have vested high power in similar bodies of men.

The last issue of the *North American Review* contains an article on the "railroad problem," in which especial reference is made to the English railroad commission, the nature of its powers and the results therefrom. From this account we draw certain statements which will be interesting and comforting during our period of expectancy. The English railway commission was organized by an Act of Parliament in 1873, and consists of three persons and two assistants. Of the three commissioners one was skilled in law, and one in railroading; and no member was allowed to have any pecuniary interest in any railway or canal company. The commission was authorized to receive all complaints of discrimination, etc., and they were invested with all authority formerly reposed in the courts, which ceased to exercise jurisdiction in railway matters except to enforce the decisions of the commissioners. This commission has power to fix all apportionment of rates for through freight to the several lines participating in the carriage. Municipal or other public corporations could lodge complaints of discrimination without proving that they were aggrieved, as investigation into the fact devolved upon the commission. The companies were required to keep a list of special and schedule rates in a place of public access, and to furnish any required information regarding their business. Access by the general public to these schedule and rate lists has proved a good provision, as well as that making any individual or corporation an informant in charges of violations. The first duty of the commissioners was to simplify the methods of procedure on applications, dispensing with certain forms and placing a company on its defense without delay. The railway and canal companies were not permitted to consolidate without the commissioners' consent and only after the terms of agreement had been thoroughly published. These were among the reforms established during the first year of the English railway commission.

"During the second year the commissioners were called upon principally to decide upon questions of discriminations on the part of railway companies between customers. Rates were proved to have been charged higher and lower than those fixed by the schedules, and the schedule rates were restored. Abatements in charges to persons agreeing to patronize a certain company were discovered on complaint and stopped. Rebates for terminal service performed by customers were stopped on complaint of parties at a corresponding station where an opportunity did not offer for the performance of similar service. A number of cases of disagreement in reference to through rates and routes were submitted to the commissioners and equitably adjusted. In one or two cases the jurisdiction of the commissioners was contested, but, this being decided in their favor, the question at issue was privately arranged. There were no appeals allowed from the decisions of the commissioners, inasmuch as the exceptions were not based on questions of law."

These few items of reform in railway management which we have outlined must be regarded as of the greatest importance in the way of securing impartial public service from the companies, and this coupled with a reduction of rates to a fair compensation for the work done is all the public desires from its carriers. That the English commission has thus far succeeded in its work during the few years it has been in power is certainly a warrant that we may expect similar benefits from a similar organization. We trust that the commission which will soon come into power in this State will be characterized by a disinterested and unhesitating enforcement of right and justice between the companies and our municipalities and individuals, for thus and thus only can the men chosen at the last election show themselves worthy of the trust committed to them by the people.

NEW TYPE WRITER.—A new type writer consists in the combination, with a finger lever and platen or roller for the paper, of a type bar, having its pivotal point and its point of connection for the connecting rod which connects the type bar with the finger lever arranged so that when the points are brought in a direct line with each other, the type will clear the roller at a convenient distance from it.

The strike of colliers at Charlarvi, in Belgium, which commenced a few days ago, is extending and assuming a threatening aspect.

News in Brief.**SIGNS of rain.**

WEATHER very hot in New York.
THE Colorado Indian war is ended.
BRITISH forces have entered Cabul.
THE walking craze has become epidemic.
LAND troubles in Ireland. Tenants refuse to pay rent.

HENRY C. CAREY, the writer on political economy, is dead.

THE United States Supreme Court is now in session at Washington.

SNOW and hail prevailed in portions of British Columbia Sunday.

THE Panama Railroad Company has declared a dividend of four per cent.

SPECIE in the Bank of Germany decreased 13,829,000 marks last week.

THE Bank of Belgium has raised its rate of discount from 2½ to 3½ per cent.

THERE are 12,000 tons of wheat at Walla Walla, W. T., awaiting shipment.

THE storm of last Saturday was quite general, and but little damage was done.

A DEFENSIVE treaty is said to have been concluded between Germany and Austria.

GREAT preparations are being made at Sacramento for the reception of General Grant.

GRAND Lodge of Good Templars for Nevada and Utah convened at Carson October 14th.

ADVISES from Montevideo state that the Cabinet has resigned and a new Ministry formed.

THE loss of the Afghans in the fight before Cabul on the 6th instant is stated at 400 killed.

SILVER in London, 52d; consols, 97 11-16; 5% United States bonds, 106½; 4s, 105½; 4½s, 109½.

YELLOW fever has recommenced in Memphis and has also appeared in Arkansas and Louisiana.

EIGHT hundred railroad employees are on a strike at Cleveland, Ohio, for an advance of wages.

EIGHT hundred barrels of potatoes were shipped a few days ago from St. John, N.B., to England.

It is proposed to consolidate the St. Louis, Kansas City and Northern Railroad with the Wabash.

TWELVE new cases of yellow fever were reported at Memphis Saturday, and five deaths occurred.

ACTIVE opposition to the employment of Chinese in railroad building prevails in British Columbia.

CONVENTION of Italian Benevolent Societies of the United States now in session at Louisville, Ky.

CALIFORNIA State Grange adjourned sine die at Oakland last Saturday. Important questions were discussed.

THE amount of public land taken by actual settlers during the late fiscal year was nearly 1,500,000 acres.

A SHIPMENT of 100,000 pounds of Arizona wheat was made lately from Maricopa, consigned to Liverpool.

RUSSIA is willing that Cabul shall be destroyed, but will not allow of the annexation of Afghanistan by England.

RUSSIA has demanded reparation from Turkey within twenty-four hours for insult to the Russian Consul General at Salonica.

THE Great Council of Geneva, Switzerland, has adjourned consideration of the separation of Church and State until May.

MEASURES to abolish slavery in Cuba is causing a crisis in the Spanish Cabinet. Ten thousand morda soldiers are sent to Cuba.

THE *London Daily News* says: If gold continues to leave England and France as it has lately, it will soon become necessary to consider measures to stop the outflow. [This money comes to pay for American products, to stop it would be repudiation.]

THE New York *Commercial Bulletin* correspondent declares, after an extended trip through the State, that the transportation question is a leading issue with the people in the interior. Oppressive railroad freight discriminations, as brought out by the Legislative investigation, has astounded the general public. If legislative remedies are prevented during the coming winter, it will not be the fault of the people, but it will rest solely with the dictatorial caucus-nominating system.

CROFUTT'S TOURIST GUIDE.—The annual revised editions of *Croft's New Overland Tourist and Pacific Coast Guide* will, hereafter, be issued on the 15th of January. The new books will contain new and important matter, embracing all the points of interest on the line of the Union and Central Pacific Railroad, but also those along 38 connecting railroads, with the adjacent country, mines, agriculture and stock-raising advantages. The work will be profusely illustrated. There is hardly a work which contains so much important and interesting matter as this little book which has, perhaps, been the means of directing many to localities where success has attended them. The publishers, the *Overland Publishing Co.*, of Chicago, Ill., are adding a new department, which contemplates the delivery of a series of descriptive lectures in this and foreign countries. The views will be on glass, appropriately colored and enormously enlarged. This department is intended to attract foreign attention, and aid in the general prosperity of all. We wish success to the enterprise, and hope to participate in the general benefits. Mr. Croft will arrive in this city at an early day to carry out the contemplated programme.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

(From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.)

FOR THE WEEK ENDING OCTOBER 7TH, 1879.
220,212.—WATER WHEEL.—D. H. Anderson, S. F.
220,337.—LIME AND CEMENT KILN.—C. Brown, Mare Island, Cal.
220,271.—FIRE-ARM.—J. M. Browning, Ogden City, Utah.
220,222.—SAFETY DEVICE FOR ELEVATORS.—James H. Custer, S. F.
220,365.—STEAM FARMING APPARATUS.—Wm. H. Foye, San Francisco.
220,366.—COMBINED STEAM HARVESTER AND THRESHER.—Wm. H. Foye, S. F.
220,367.—DOUBLE-ACTIVE REVERSIBLE GANG PLOW.—Wm. H. Foye, S. F.
220,253.—AUTOMATIC GRIP FOR ROPE RAILWAYS.—Henry S. Grace, S. F.
220,254.—MACHINE FOR SEAMING CANS.—Robert D. Hume, San Francisco.
220,387.—VENTILATING APPARATUS FOR MINES.—J. Kay and S. Rockefeller, Bodie, Cal.
220,246.—ROTARY ENGINE.—B. E. Letang, San Leandro.
220,403.—WINDLASS AND DERRICK FOR WELLS.—Benj. F. Mull, Merced, Cal.
220,304.—EXPLOSIVE COMPOUND.—John Pattison, Nevada City, Cal.
220,454.—HONEY EXTRACTOR.—G. W. Williams, San Diego, Cal.
220,326.—TOE-WEIGHT FOR HORSES.—Wm. Zartmad, Petaluma, Cal.
220,299.—PLANING MACHINE.—J. W. Metcalf, San Jose.
220,325.—SPRING GUN.—R. Wylie, Napa, Cal.
220,376.—WHEELY-TRAMMEL.—S. F. Chichovich, S. F.
NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

MACHINERY FOR REDUCING OLD STEEL RAILROAD RAILS TO MERCHANTABLE BARS.—Burrongs P. Brunner, S. F. No. 219,616. Dated Sept. 16th, 1879. In the working of steel it is of the highest importance that any disturbance of the fibers of the metal shall take place equally throughout the mass. If an unequal disturbance of the fibers occurs, it leaves the metal in a condition of unequal tension highly detrimental to its subsequent manufacture. Heretofore, in re-rolling and reducing steel railway rails, it has been customary to split the web of the rail at one pass through a cutter, in order to prepare the pieces for the subsequent action of reducing rollers. The web being comparatively thin, there is a necessary amount of drawing of the web of the rail incident to the impact of the knives on the web, and this drawing, without any corresponding drawing of the flange and head, leaves the fibers of the metal in the web elongated in relation to the fibers in the head and flange. This unequal tension or condition of the fiber, when once produced, is impossible to eradicate by any subsequent rolling or working, and is a great drawback to the utilization of the steel. The object of Mr. Brunner is to overcome this difficulty and provide a means whereby worn-out steel rails may be re-rolled into merchantable bar or other steel in a cheap and convenient manner; and the invention consists in rollers having grooves or passes, one of which is provided with a cutter or cutters, this groove or pass provided with a cutter being designed and operated simultaneously to split the rail along the line of the web and compass and draw out the head and flange portion of the rail, the other grooves or passes operating subsequently to reduce the head or flange sections to merchantable bars of the form desired.

VENTILATING APPARATUS FOR MINES.—Joel Kay and Simon Rockefeller, Bodie, Mono Co., Cal. No. 220,387. Dated Oct. 7th, 1879. This invention relates to certain improvements in apparatus for ventilating mines, tunnels and other excavations or chambers in which foul air, gases or vapors are liable to accumulate; and it consists in the employment of a steam boiler, into the chimney or stack of which a pipe or tube is led from the point which is to be ventilated. This pipe turns upward within the stack, and a steam pipe is led from the boiler into the pipe, discharging toward or up the chimney or stack, so as to create a draft which will draw the air or gases through the tube, and discharge it to be carried out by the draft in the chimney or stack. By this apparatus the ventilation may be more readily and thoroughly secured than by any device now in use.

EXTENSION LADDER.—Oscar Marshall, Stockton, Cal. No. 219,749. Dated Sept. 16th, 1879. This invention relates to certain improvements in the method of operating extension or other ladders, derrick masts, and other apparatus which it is necessary to frequently raise and lower; and it consists in a novel combination of drums or rollers, and a movable fulcrum mounted upon a suitable frame-work, so that the ropes from these drums act consecutively upon the ladders, the first drum acting to raise the ladder or mast to a certain position, and the second one completing its elevation, after which the apparatus is set to any desired incline or position by the aid of the two,

WINDLASS AND DERRICK FOR BORING ARTESIAN WELLS.—Benjamin F. Mull, Merced, Cal. No. 220,403. Dated October 7th, 1879. This invention relates to an improved windlass and derrick for artesian well-boring, and consists: First, in a novel construction of the windlass, so that it may be worked by hand or horse, or steam power, and by which it may be worked by cog or friction gearing for more or less speed, as desired. Second, in forming the derrick of light sections of boiler-iron connected together in a peculiar manner, by which means he is enabled to form a light, high derrick which may be easily separated in sections, so as to be transported from place to place without difficulty.

SPRING GUNS.—Richard Wylie, Napa, Cal. No. 220,325. Dated Oct. 7th, 1879. This device relates to an apparatus for throwing missiles, projectiles or arrows; and it consists of a gun having a barrel, suitably connected with a stock and having a slot in its lower part. A driving-block for the arrow or projectile moves in the barrel, and has a stem projecting down through the slot, so as to have the firing elastic straps attached to it. These straps are contained in a chamber beneath the barrel, and have one end secured at the front, so that their tension may be regulated. The weapon may be properly sighted, and is very accurate.

PLANING AND MATCHING MACHINE.—John W. Metcalf, San Jose, Cal. No. 220,299. Dated, Oct. 7th. This invention relates to an improvement in wood-working machinery, and it appertains particularly to that class of machines wherein by the passing of a board through a planing machine to divide it longitudinally into two boards, each of the two are planed on both sides, and each tongued on one edge and grooved on the other, so as to form matched stuff, which may be headed at the same time; and the invention further consists in alternating the planing and the grooving knives on the same shaft.

SELF-FASTENING TOE-WEIGHT.—Wm. Zartman, Petaluma, Cal. No. 220,326. Dated, Oct. 7th, 1879. This invention relates to an improved toe-weight for horses, and consists in a peculiar construction of the spur or clip and weight, by which the weight is firmly secured to the shoe without the necessity of using any bolts, screws, or straps to keep it in position, so that the weight is made self-fastening.

Back Numbers Wanted.

The following volumes and single copies of the MINING AND SCIENTIFIC PRESS are wanted at this office, for which a reasonable price is offered:

Year.	Volume.	2 Complete volumes, 1st half (of year).
1870	20	2 Copies of No. 1, Jan. 1st.
1870	20	1 Copy each of No. 1, Jan. 1st, 3 of Jan. 14th, 7 Feb. 11th, 6 Feb. 4th.
1870	21	1 Copy of No. 7, August 13th.
1871	22	5 Copies of No. 1, Jan. 7th.
1871	22	3 Copies of No. 5, Feb. 4th.
1871	22	1 Copy of No. 3, Jan. 21st, 6 of Feb. 2d, and 1 of May 1st.
1871	23	1 Copy of No. 3, July 15th, and 9 Sept. 2d.
1872	24	2 Copies of No. 4, Jan. 27th.
1872	24	3 Copies of No. 7, Feb. 17th.
1872	24	2 Copies of No. 17, April 27th.
1872	25	1 Copy of No. 10.
1872	25	1 Complete volume, last half (of year).
1873	26	3 Copies of No. 8, Feb. 22d.
1873	26	3 Copies of No. 9, March 1st.
1873	26	3 Copies of No. 10, March 8th.
1873	26	1 Copy of No. 7, Feb. 15th.
1873	27	3 Copies of No. 20, Nov. 15th.
1873	27	4 Copies of No. 21, Nov. 22d.
1873	27	3 Copies of No. 24, Dec. 13th.
1875	30	1 Copy of No. 4, Jan. 23rd.
1875	30	1 Copy of No. 5, Jan. 30th.
1875	30	1 Copy of No. 8, Feb. 20th.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. THARP—San Francisco.
B. W. CROWELL—California.
A. C. KNOX—Pacific Coast.
S. V. BLAKESLEY—State of Nevada.
G. W. McCRAW—Santa Clara county.
MILTON KENNEDY—Kern and Inyo counties.
J. B. BACHELDER—Shasta County, Cal.
H. H. MESSENGER—Arizona.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographical. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

HOW TO STOP THIS PAPER.—It is not a benevolent task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

EXPERIMENTAL MACHINERY. drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Captains, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER,

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

Books for Miners and Millmen

KUSTEL'S ROASTING OF GOLD AND SILVER ORES, and the extraction of their respective metals without quicksilver. Illustrated. 142 pages. 1870. A valuable and carefully written work. Postpaid, \$2.50. Published and sold by Dewey & Co., S. F.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arseniures, and gold and silver ores generally, with 120 lithographic diagrams. 1871. This work is unequalled by any other published embracing the subjects treated. Postpaid, \$7.50. Printed and sold by Dewey & Co., S. F.

PHILLIPS' EXPLORERS, MINERS AND METALLURGISTS COMPANION, comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy. \$72 pages and 83 illustrations. A most valuable and comprehensive book of reference to prospectors and practical miners. Postpaid, \$10.50. Sold by Dewey & Co., S. F.

ARON'S TESTING AND WORKING SILVER ORES.—Illustrated. 114 pages. 1876. A useful and practical work, free from technicalities and extremely serviceable for miners' use. Postpaid, \$2. Published and sold by Dewey & Co., S. F.

COFF'S HANDBOOK OF MINING LAWS.—Containing the U. S. Mining Laws, Digest of Decisions, Forms, etc., 1877. Pocket size, and very handy and convenient for miners. Postpaid, \$1.00. Sold by Dewey & Co., S. F.

FRASER & CHALMERS
 STEAM ENGINES, BOILERS, STAMP MILLS, FRUEVANNERS
 (and Machinery) for Systematic Mining, Milling, Smelting and Concentration of Ores.
 No. 145 Fulton St., CHICAGO, ILL.

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade

PATENTED IN THE UNITED STATES PATENT OFFICE.

THE CALIFORNIA POWDER WORKS,

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and HERCULES Powder.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated. With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

Dunham, Carrigan & Co.,

Nos. 107, 109 & 111 Front Street, S. F.

Lathe Without Saw Attachments.

This lathe has been made especially to meet a want felt by many for a really good and substantially made Foot-Lathe at a reasonable price, and we think that it is by far the best Lathe ever placed on the market at the price asked. The bed, head, and tail stocks are of iron; the spindles of steel. The bearing of the head stock is cast-iron, so that the wear can be easily taken up.

Material eighteen inches long and eight inches in diameter can be turned upon it. The pieces that accompany this Lathe without extra charge are two T rests, two plan-centers, one spur center for wood turning, and one face plate.

Price of Lathe without Saw Attachments.....\$45. Price of Lathe with Scroll Saw Attachment.....\$55
 Price of Lathe with both Scroll and Circular Saws, \$70.

Trump Drill Chuck.

Chuck for drills $\frac{1}{2}$ and under,
 Price.....\$1.50
 Chuck, for drills $\frac{3}{4}$ and under,
 Price.....\$2.25
 They are made on solid steel
 plug, centered and readily fitted
 to Lathe or Drill Press.
 SEND FOR CIRCULAR.

MINERAL LUBRICATING OILS.

Both Dark and Light in Color, and Gravities to Suit all Classes of Machinery.

For use in all Saw Mills, Flouring Mills, Quartz Mills, Foundries and Machine Shops, and Railroads.

Natural Dark West Virginia Lubricating Oils,

FROM 19 DEG. TO 23 DEG. GRAVITY.

LIGHT PARAFFINE LUBRICATING OILS FROM 24 DEG. TO 28 DEG. GRAVITY.

CYLINDER OILS for use in all Cylinders.

A Full Stock of LARD OIL, SPERM OIL and other Lubricating Oils constantly on hand. Also

High Fire Test Water White Illuminating Oils,
 FOR USE WHERE ABSOLUTE SAFETY IS REQUIRED.

Oil House of F. B. Taylor & Co.,

120 and 122 Front Street, - - - San Francisco.

From 1-4 to 10,000 lbs. Weight.

True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. Gearing of all kinds. Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc. 12,000 Crank Shafts of this Steel now running proved superior to wrought iron. CRANK SHAFTS, CROSSHEADS and GEARING, specialties.

Circulars and Price Lists free. Address

STEEL CASTINGS. **Chester Steel Castings Co.**
 Works, Chester, Pennsylvania. 407 Library St., Philadelphia

SHEET IRON PIPE.

SHEET IRON PIPE.

Mining Machinery Depot, PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Amusements.

Box office, for sale of reserved seats, now open.

Patents for Mining and Farming Lands.

Having complete arrangements with competent and reliable parties in Washington City, by which we are able to secure prompt and careful attention to law business there, we are prepared to assist Mill and Mine, Canal and Ditch owners in securing patents for their lands, mines and claims, in addition to our general line of patent business.

Many who are acquainted with the manner in which this business has heretofore been conducted, (with or without assistance by local attorneys), will see at once the great advantage of patronizing an establishment that is thoroughly organized and has its representatives in Washington to look after and prosecute their applications before the Commissioner of the General Land Office. The business on this Coast will be attended to personally by a member of our firm, and satisfaction will be given in all respects.

Correspondence from persons desirous of securing patents for Lands, Mines, Mill Sites, Canal and Ditch property, promptly attended to.

Applicants for patents for mining and farming land, whose claims have been delayed for any reason, will find it to their advantage to consult with us and in case of necessity secure the services of our home and Washington branch agency.

DEWEY & CO.,

Solicitors of Patents for Lands, Mines and Inventions, MINING AND SCIENTIFIC PRESS OFFICE, No 202 Sansome St., San Francisco.

GIANT POWDER

MANUFACTURED UNDER A NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive.

Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. 47 Triple Force Caps and all Grades of Fuse.

SAN FRANCISCO, CAL.

VULCAN BLASTING POWDER.

The Strongest, Safest, Most Uniform and Reliable "HIGH EXPLOSIVE" Manufactured on the Coast.

MINERS TESTIFY THAT IT IS FREE FROM OBJECTIONABLE FUMES.

We call the attention of all desiring such a Powder to our various grades, which we are prepared to sell at LOWEST RATES.

No. 1.—Equalling Liquid Nitro-Glycerine in Strength. We recommend this Grade in extremely hard rock, boulders, iron, etc.

No. 2.—Will do the work thoroughly in all but the hardest kinds of rock.

No. 3.—For bench work, pipe-clay, soft and shelly rock, outside work and quarrying.

Single and Triple Force Caps, Fuse of all Grades, Vulcan Powder Thawing Boxes, Batteries and Exploders, For Sale at the Lowest Rates.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

A. S. HALLIDIE.

VOLUME XXXIX
Number 17.

California Maintains Her Prestige Abroad.

While Dakota, Colorado and other intervening countries have, for the past few years, been receiving a large share of attention, this has not prevented free investments in the mines of California, which has retained her hold on the confidence of the outside world in a manner hardly to have been expected, considering the formidable character of her competitors. While our hydraulic mines have, of late, been much sought after in the East, our gold-bearing quartz veins have been by no means neglected. The lodes in the Bodie district seem to have enjoyed a preference, for the reason that such of them as are already brought into an actively productive condition have all yielded liberally, while those that are being prospected show remarkably well.

The most promising claims in this district appear to lie in groups or bunches, having often some one or more noted mine for a center. Thus, we find near Bodie Bluff, the Standard with the Bulwer, Bodie, Bechtel and other especially hopeful properties clustered around it. A little further north, near Queen Bee hill, occurs the original Noonday with the South Noonday, Red Cloud, Booker, etc., encircling it. In this, as in the Standard series further north, the work of exploitation, which is being pushed with vigor, points to the existence of valuable ore bodies. Hence a lively interest is kept up in these mines, causing shareholders to respond to the calls of directors for financial aid with alacrity, notwithstanding ore developments have, in some instances, been delayed to a vexatious extent. But a good gold mine is not to be dug out in a day, and, in view of what has been achieved in this district, shareholders evince good sense in holding on, in all cases, where work is being judiciously carried on and due economy observed. The former owners of the Standard, Bulwer and Bodie lost the chance of being made millionaires by letting go too soon, an experience that others seem disposed to profit by.

The Standard has enjoyed the benefits of an excellent administration from the first, nor has that of the other mines near by been at all faulty. This has also been the case with the other group, the management of the South Noonday, like that of the Standard, having been exceptionally good, this mine being also conspicuous for both the evidence of inherent merit and its favorable surroundings.

As regards investments in hydraulic mines, the bare along the Trinity and Klamath rivers appear to have the call at present, and it is said that a good deal of Eastern money is likely to be put into the mines in these northern counties on the recommendation of certain of our leading experts. As the mines in these out-lying localities remain in a comparatively primitive condition, it is probable enough that they present some advantages not common to the older districts; and may, therefore, well deserve the preference accorded them by parties just entering the field. We are of the opinion, in fact, that the opportunities for engaging in this branch of mining, though perhaps not very numerous, are exceptionally good in these northern counties, the gravel there being of high grade and the conditions generally favorable.

The committee of the San Francisco Chamber of Commerce appointed to the congress discussing the construction of the Darien canal, reported that the cost was estimated at 1,070 millions of francs, or \$214,000,000. It was also estimated that in ten years the annual tonnage would amount to seven and a quarter million tons. The toll of \$3 per ton was deemed too high by the committee, when articles like wheat and certain ores were considered. The report was signed by Christian Christiansen and Elie Lazard.

The steamship *Great Eastern* is to be fitted up with new boilers and machinery at a cost of £140,000, to carry cattle between London and Texas. She is capable of holding 2,000 head of cattle and 56,000 head of sheep.

Profits of Mining.

An exchange says: "No matter how fascinating, no business can be permanent that is not profitable as a whole. Gold and silver mining in the United States stands this test better than any other business, and to-day is better established than ever before." Aside from the speculative tendencies, there can be no question that active mining is a profitable business, but there are two elements that have cast a shadow upon this business, and which will always deter many capable individuals from engaging in it; these are speculating in the mine as property, and secondly, speculating in the stocks as representatives of its value. In the first instance this business is conducted very much as are any sales of real estate, with the only exception that the precious metal in the claim is the prize contended for. The prospector who makes a find, naturally desires to sell it as a whole, or at least a part interest in it, for the purpose of ob-

taining capital to work it. There is nothing very objectionable about this, unless deception is practiced. "The mine is there, go and see for yourself, or send an expert on whom you can rely." But when the mine assumes the shape of a corporation with a gigantic capital stock, which is supposed to represent a probable theoretical value, even magnified then in proportion to the sanguine imagination of the owners, the profits are not so apparent, because the element of mining does not enter in these stock transactions, they are mere "bets." It is useless to say that dividends are paid to stockholders. The stockholders are generally ephemeral, and do not hold on long enough to obtain dividends. The temptations are strong to rush into the stock business and acquire a fortune on a rise, but this is not investing in the mining business as it should be understood. This latter is investing in and actually working a mine, and the distinction should always be made when speaking of profits. The individual who invests his money in any business and leaves others to control it, cannot be said to be in the business, he is simply a "goose to be plucked" whenever the occasion may offer. With this modification of the matter, therefore, we agree with the statement that the mining business "has more elements of lasting strength, and of certain and regular profit than many other business adventures."

ADVANCE IN QUICKSILVER.—The price of quicksilver in this market was recently depressed to 34 and 34½ cents, and many sales were alleged to have been made at both figures. These prices existed October 9th, and at that date the quotation in London was £9 per bottle, on the 14th the price went up to £7 in London and 40 cents here. Since then private cables announced the price at £9. The cause of the advance is not given. It is known that there have been terrible floods in Spain, and there are rumors that the Almaden quicksilver mine in that country has been flooded. This would be a sufficient cause for the advance. Here stocks have become wonderfully scarce, and the price has been put up to 55 cents, with reported sales at that figure.

Boiler Feeder.

The Cope & Maxwell Manufacturing Company, of Hamilton, Ohio, of which company Messrs. Parke & Lacy, 417 Market street, San Francisco, agents, have devised an excellent vertical crank and fly-wheel combined well-pump and boiler feeder, illustrated on this page, which is recommended for situations where the water is within the limit of suction, say 25 feet below the pump to source of supply. In cases where the water is beyond the limit or over 25 feet, the well pump is lowered down to the proper distance.

By means of the well pump cold water from a cistern, well or stream may be raised and delivered into a reservoir, tank or heater, and, after being heated, may be conducted to the boiler feed pump, and by it forced whilst hot into the boiler, thus accomplishing a double duty, a work that can be performed by no other single machine, meeting a necessity and fulfilling conditions in the line of supplying steam boilers never before provided for.

The well pump is made somewhat larger in capacity than the boiler feed pump; as they make stroke for stroke with each other, there will be an excess of water delivered by the lower pump which can be used for other purposes.

The material and workmanship in these machines are of the very best quality, and no pains is spared to make them the most perfect boiler feed pump in the market.

In situations where the feed water cannot be otherwise heated, the exhaust steam from the steam cylinder of the boiler feed pump can be turned into the suction pipe and condensed, forming a vacuum in the steam cylinder to the ex-

haust steam, or the exhaust pipe can be turned into the tank or cistern from which the pump takes its supply of water, and thus utilize the heat from the exhaust steam.

These boiler feed pumps are made small enough to supply the smallest threshing, farm, road or domestic engine or boiler, and large enough to supply a battery of two or three horizontal boilers.

For anything larger, the company make a horizontal crank and fly-wheel engine, with double-acting pump.

Vertical Crank and Fly-Wheel Boiler Feeder.

Room for Inventions.

The demands made upon scientific knowledge far exceed the supply. Although we may be said to have arrived at an advanced stage of learning, we undoubtedly possess but a limited amount when comparison is made with the necessities which as yet know no law. There are so many theories broached upon important subjects that fully the major portion of the requirements of manufacturers and miners are the victims of experiment. We want improvements in processes—not experimental improvements, but practical working and satisfactory processes, capable of substantial accomplishment of the theories claimed for them. Employers of steam engines demand more power from the enormous quantity of fuel consumed, waste products are waiting to be utilized, streams and atmospheres are crying out for relief from the pollution that is being thrown into them.

It is true inventors are endeavoring to provide means of supplying these demands, but frequently fail to satisfy the demand for the adaptation of new principles because the knowledge of the latter are incomplete. Discovery is usually the basis of invention, and the greatest utilities have been thus obtained, rather than by the exercise of invention upon old knowledge acquired. A machine for completely converting heat into mechanical force is required, but so far our scientific knowledge of the properties of heat has not led us up to the point of discovery upon which to base an invention of that kind. One invention leads to an innumerable chain of inventions, all of them more or less improvements, but still inventions. The field is immense, with abundance of room for inventors.

U. S. GEODETIC SURVEY.—We are informed by a recent number of the *Reno Gazette* that the astronomical and geodetic party under charge of Prof. Davidson has finished its work at Station Round Top in the Sierra Nevada, south of the Carson pass, but not before it had encountered two very severe storms of snow and wind, in which the thermometer was nearly zero for many days. When they came out the snow averaged four feet in depth, and the men and animals sank three feet into it. The astronomical and geodetic work at Round Top has been successfully executed in less than two months, although the lines to distant stations in the Coast Range are from 120 to 160 miles in length, and pass through the dense smoke stratum of the Sacramento valley. The lines are longer than any ever undertaken in Europe. Nevertheless it is understood that the results are in the highest degree satisfactory. A special series of observations was made to determine the coefficient of refraction at these great elevations. To exhibit the peculiar orographical features of Round Top (named apparently by the rule of contraries because it is a great, sharp backbone), one of the officers has made a topographical survey of the mountain; whilst Watkins, the celebrated Yosemite photographer of San Francisco, has executed some fine large photos of the mountain, to illustrate its general and detailed characteristics. Prof. Davidson has returned from the mountains, and will, at the next meeting of the California Academy of Sciences, read a paper on the subject of the work accomplished by his party. This we shall publish after it has been read.

NICKEL MINING IN NORWAY.—It is alleged by the *London Times*, that Norway is the principal source of the nickel supply, and furnishes quite one-third of the yield of the world. The first mine was opened in 1846, by an English company, in the valley of Espedal, in the mountain district of Sondre-Gudbrandsdal, but this was closed in 1857 in consequence of the difficulty of the approach, and the absence of communications. Subsequently to this, mines were opened at Ringerike and Bamble, near Skon, and from 1861-5 there were 11 nickel mines worked, averaging 3,450 tons per annum. In the latter year the production rose to 5,200 tons from 14 mines, and it gradually increased until 1875, when it attained its maximum at 34,550 tons. The greater part of this yield is exported in the shape of ore.

PERSONAL.—Messrs. Dewey & Ewer, publishers and proprietors of the Press, have gone to Los Angeles to attend the Southern California Horticultural and Agricultural fairs. We can recommend these gentlemen to any one whom they may meet as modest and gentlemanly persons, generally well behaved and highly esteemed at home, and believed to be capable of withstanding a moderate amount of temptation. Therefore, we feel confident they will do themselves and us much credit by their general deportment, especially as they are going to associate with so bright and upright a people as Los Angeles. May they return better than they went!

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

El Dorado Mines.

EDITORS PRESS:—I have been prevented by causes beyond my control from sooner resuming my letters, but I will now try again.

The Bower Mine,

On the Greenwood seam belt, was where, metaphorically speaking, I left you standing, and before following the belt down towards the Middle Fork of the American river, we will look at the Bower mine a little further. The late rains have washed off the dust, and it is only round that section that the plague of dust could be realized, and now wherever cuts, shafts or grades have been made, veins of soft and hard quartz are exposed in every direction, and the ledge can be easily traced. The mine itself forms a basin of 40 acres, with rising banks around, and is nearly encircled by the California Water Co.'s canal, thus securing an ample supply of water. Mr. Bower is now engaged in putting in a water blast, as foul air has for some weeks delayed progress in his tunnel, but he still expects in a few weeks to be able to raise to the surface and begin to develop in earnest, when I hope the company will be handsomely repaid for their great undertaking, by many years of remunerative work. Proceeding northward we come to the mine owned by

Blabtriu & Co.,

Who have been steadily prospecting till a few weeks ago, when scarcity of water induced them to close down for a while. Their present workings are on a slide or outpour from the main belt, and this being in the American canyon itself afforded them a chance to work in pay from the start. They will have to run off a large amount of frontage yet ere they can touch the main belt, but while they can fully make expenses in doing so they are quite satisfied, as who would not in these times! Crossing the canyon we next come to the

Von Bremer Mine,

It being the next in operation, though several other promising locations exist. Mr. Henry Von Bremer & Co. have done a large amount of work on their claim, which has a good natural outlet into the canyon, and have still a promising and I believe a profitable mine. Following the seam belt across the range (a rough undertaking) there is little to notice till we sight the Middle Fork. Two large water-wheels and the usual wheelbarrows and gang planks show that some still have faith in the "bars," and on the bank of the river we come to the

Dolly Varden,

A claim recently relocated, Dr. G. W. Haudy, of Oakland, being the new owner. The work previously done was from the edge of the river, two good leads being discovered, but the depth of bank and price of water made the work at once dangerous and too expensive under the old system of hydraulic mining. One of the former proprietors losing his life by a slide the mine was shut down, and has since passed from hand to hand unimproved, till relocated by its present owners. I understand that it is their intention at an early date to open the Dolly Varden with all the modern improvements; and I believe there is every warrant for their doing so, as this claim will make a great outlet for an almost exhaustless portion of the "belt." This now crosses the river into Placer county, I will therefore leave the porphyry for the present, and after looking into

The Wine Garden,

A pleasant little nook reclaimed from the wild and rocky river bank and now a blooming orchard and vineyard, planted and cared for by Mr. William Wiggins, the genial host, and his brother, both old-time miners and long residents, and tasting some of his excellent vintage and luscious fruit will travel on to the

Sardine Mine,

On Main Bar. In the early days of river mining this claim proved so rich that reports of the prospects obtained are almost fabulous, in these days of poor diggings; but here again the old-time system of mining proved inadequate. The great expense of opening, the limited time of working, and chance of losing all the machinery each fall, prevented the Sardine mine from being worked, but those who had faith waited from year to year till this last summer a company was formed and under the management of Mr. Thomas Sissions, to whose active energy and mining ability the entire enterprise is really due. They are now sinking on the bank of the river, above all average high-water mark, and at a depth of 75 feet propose to drift towards and under the river and take out all that remains of the fabulous wealth said to exist there. The shaft is now down nearly 50 feet and a small pump keeps it clear of water, but Mr. Sissions has a larger one in readiness for an emergency, and is preparing for a winter campaign by housing his hoisting works and pumps. It will take him eight or ten weeks yet to gain the required depth, the rock being very hard, and he will then have to drift some 40 or 60 feet to tap the gravel. This is a claim of great

expectations, and with a not unreasonable prospect of their fulfillment.

The Golden Ophir.

Returning up the canyon we cross over from the Cederberg (a once rich and notable quartz mine, and which will I think again be heard from) we pass over to the Golden Ophir, a portion of which was formerly known as the "International." This mine is composed of slate veins with quartz seams, but from the slate free gold and rich sulphurets are obtained. Col. T. G. Bilty, who has long been an earnest and successful factor in developing the Greenwood mines and introducing capital, has spent much time and coin in opening up this claim. New machinery has been recently erected by Mr. F. A. Huntington and a Mr. Howland of your city, on a new principle; and after one of those delays which will occur in the best regulated mines, the jovial and indefatigable Colonel has succeeded in getting his mine and mill in running order, and under the new ownership, as I understand of Judge Lawrence and others, the mill is now at work, but as my limits have been reached I must reserve fuller remarks of this property until my next.

Greenwood, Oct. 14th, 1879.

Nevada Mines, Copper, Etc.

EDITORS PRESS:—From Aurora northward towards Virginia City, at about half the distance, a few mining enterprises of much real value are located, but to which we have rarely seen reference made.

The first is Pine Grove, 15 miles east from Compton's ranch, reached by a trail or much longer winding road over a high, rugged mountain range. Here a fine gold and silver vein, of good workable thickness, runs lengthwise along a spur of the mountain some three miles. The mines on this vein have been worked 14 years; but at first, in the uncertainty of the dip and other features of the lead, many tunnels were run in a wrong direction and much labor lost. Gradually this difficulty was overcome, till now, in a knowledge of facts learned by experience, work is pursued with a fair uniform remunerative yield to the owners. A few shafts have been sunk, the main one 300 feet deep; but the principal work is by tunnels, one or two of which are 1,000 feet in length. The various claims have at length been nearly all consolidated into two, and worked systematically, of which the upper one is superintended and mostly owned by Mr. D. Wilson; the lower one is directed by C. W. Fish. The town or, rather, two villages, may include 400 people, of which many have families. From what we saw and could learn, we judged the community to be more than usually peaceable and diligent in labor, prospering in all real interests. This may be owing to a remarkable fact that here no mining work is done on the Sabbath, a regulation observed by Mr. Wilson from an early day, when he first came to the locality. The results of such a course are always decidedly advantageous in improved morals, better social good order, greater intelligence, more general good health, longer life, and finally, in increased wealth. We know of only one other mining camp or claim observing this regulation in the State of Nevada, and that is a new enterprise, under the direction of ex-Governor Blaisdell, eight miles southeast of Pine Grove, which we could not, at this time, visit.

Copper Mines.

Thirty miles north of Compton's on the northeast side of Smith's valley, in the foothills, is one of four copper mines in that region of very great interest. It is the mine of Ludwick & Carter, and runs into the mountain between lime and porphyry walls in connection with the best of iron ore. The copper exists in its various compounds, often remarkably rich—60% or 70%—and in immense quantity. It is not an even, regular vein, but lies more in vast deposits, connected sometimes by only a seam, and again by an inch or two-inch vein, corresponding to the common mineral veins in lime. The mine is a beautiful one, entirely dry, admirably worked, and easily entered by a tunnel. The ore is brought out, carefully sorted, and the best sent by freight to Dayton for refining, to be manufactured into bluestone or sulphate of copper for the purpose of silver reduction. This copper mine, under the superintendency of Mr. Ludwick, is one of the neatest and most pleasant mines we ever visited.

Again, over the rugged range, three miles east, is another admirable copper mine, called Daniels, superintended Mr. J. McConnell. It is dry, like the previous, and farther across, very uniform in character, easily quarried, but not quite so rich. It is a splendid mine, and a mile or two in length. One very remarkable feature of it is the natural bluestone or sulphate, in immense seams, some an inch and a half in thickness, separated by thin clay deposits, and all appearing as perfect as the crystallized manufactured sulphate. This natural production is a great rarity in the world—so uncommon that a Bonanza chemist of Story county denied to us the possibility of its existence. Yet there it is, clear and distinct, in scores or hundreds of layers, in this Daniels mine. The explanation for it is that the vein is in a dry region, and is located so as never to be reached by rain to dissolve it away, as would be the case elsewhere.

Another copper mine is two miles south of the

last, bigger in the range, and owned mostly by Mr. Spragg. It is the oldest of all, well developed, but not now worked in force. We did not visit it, but were informed of its worth by others. Besides these three, there are a few others to be developed, if there were a greater demand and better market for copper. Yet one on a low knoll in the valley has formerly been quite vigorously mined, though it is now lying entirely inactive.

These were the best mines we visited on our trip, as we returned to the point whence we started four months since. On the whole, we have been more and more impressed by the evident number, variety, extent and richness of the mines of the State of Nevada. The work of their development has assuredly only commenced, while possibly not a tenth part of the valuable leads are yet discovered. Many once worked and abandoned as worthless are found to have been a failure only through the ignorance of their first claimants, and now are yielding large regular returns, and are likely to do so for ages to come. Yet surely there are also thousands which have been proved really worthless, teaching the lesson that the greatest care is needed and the best judgment in determining upon a mining enterprise. S. V. B.

OCTOBER IN THE SIERRA.—Upon the above subject the *Truckee Republican* says: The present winter begins with unusual severity, and in mid-autumn. For an entire week furious storms and whirling masses of snow have prevailed with only brief interruptions. Snow covers the summits to a depth of an least two feet. Extreme cold has accompanied this October storm. Icicles, frost and frozen roads betoken the strangeness of the frock which nature seems to be taking. The terrified owners of herds of cattle and flocks of sheep, who are accustomed to remain in the mountains till the last of October, are hurrying their stock over the summit with all the rapidity possible. Although they know each turn and angle of the well-beaten highway, yet the passing of the snow-covered Sierra is attended with the utmost difficulty and danger. A fierce hurricane, only last week, twisted hundreds of forest pines from their roots, and hurled them crashing to the earth. Caught in such a gale, the herds and flocks of the mountains would fare badly, and many of the animals would doubtless perish. Caught on the summits in a snow-storm, without hay or feed of any kind, the danger of destruction would be most imminent. Even at best, with such cold, piercing weather as we are having, the journey must be fraught with toil, exposure and dread.

NEW GOLD FIELDS IN TASMANIA.—New gold fields have been discovered in Tasmania. At least so says the *Melbourne Argus* on the authority of its Launceston correspondent, who announces the advent in his city of a man with 70 ounces of gold, obtained on the Pieman river, west coast of Tasmania, and the prompt departure from Launceston of a large number of diggers, bound for the new workings. These men have embarked in a coasting steamer which will convey them to Pieman river, whence they tramp it for 70 miles through the bush to the locality that has proved so productive of the precious metal. A vessel named the *Little Maid*, which arrived at Circular Head on the 23d of last May, brought the news that a party of three men were "realizing" an ounce and a half of gold per diem at the diggings. This intelligence naturally caused considerable excitement in Melbourne, whence it appears to have been telegraphed to all parts of the Australian continent. The population of Tasmania may be expected to increase with extraordinary rapidity should further exploration and experiment confirm the statements of the lucky diggers who have already come into Launceston with their treasure.

PACIFIC COAST PETROLEUM.—The San Jose *Mercury* informs us of the successful termination of oil prospecting. It says: After many discouragements and disappointments, sufficient to have caused most people to have abandoned the undertaking, the oil-borers in the Moody gulch, in this county, in the Santa Cruz mountains, have met with grand success. A large number of wells have been bored in this and San Mateo counties, but in none of them has petroleum been found in paying quantities, until on Friday last the Dull brothers, employed by the Santa Clara Petroleum Company, at a depth of 600 feet, while boring through a stratum in which they least expected to find oil, struck a vein which spouted petroleum to a height of over 100 feet above the top of the well. Being unprepared for such a surprise, it is estimated that more than 100 barrels of oil ran to waste. After a time the flow subsided, to be resumed at regular intervals ever since. All the available help in the vicinity of the well was immediately put to work, and the second flow was prepared for and all saved. The excitement in the oil region is intense. The petroleum is of a superior quality.

EUCALYPTUS VS. PHYLLOXERA.—According to *Les Moudes*, the ravages of the phylloxera may be checked by planting the eucalyptus near the vineyards. It is contended by the writer of the article that, from the analogy of imported insects, such as the housebug, the cockroach, the American apple-blight, etc., there are no grounds for expecting that the pest of the vines will disappear of itself.

The Caribou Mines, Idaho.

A miner in a late issue of the *Denver Tribune*, speaking of the Upper Snake river and its tributaries says, with reference to the Caribou mines:

We have here in this section of Idaho one of the best deposits in the Territory, extending from Iowa gulch on the east, to Keenan gulch on the west, a distance of ten miles. The deposits are from 10 to 40 feet in depth, and resemble somewhat that country in and about Forest Hill, in California, which yielded \$15,000,000 in gold for only two miles in length, and is still worked with good results.

The importance of Caribou as a gold-bearing district is no longer a question of doubt. For many years it has been known that gold existed through the various canyons that make their way from Caribou mountain and empty into Snake river. Extensive placer and hydraulic mining is now being done on Iowa bar, only two and one-half miles down the northern slope of Old Caribou. The annual yield of gold from the placers has at one time and another fluctuated considerably.

Quartz was first discovered in 1874, by some Montana miners on the southern slope and near the summit of Caribou mountain, and at the head of Tin Cup, a stream which empties into Salt river. The discovery was made by Dan Griffith and Jeff Thompson, who did some prospecting on the mountain. In those days quartz attracted but little, if any attention. After years of prospecting through Nevada and Utah, Griffith came to the conclusion to return to Caribou and further test his first find, which he did, meeting with results that induced him to make a location called the Oneida, the first quartz claim made and discovered on Caribou mountain.

A few years since a prospector well known all over the coast, named John Robinson, wandered in here, and after a careful examination of the camp and its surroundings, came to the conclusion from the amount of auriferous gravel deposited below, that there must be somewhere in the mountains huge quartz veins of immense value, and to find them, he at once went to work. In prospecting the mountain he found a porphyry belt about a half mile wide, lying on the northern slope of the mountain, running in a northwesterly and southeasterly direction, in which veins are found, and carry the same general course as the porphyry. He made a location called the Robinson, about 1,500 feet northwesterly from the Oneida, and at the head of Bilk gulch, every foot of which prospects well in gold from the side lines of the Robinson to where they are working the placers.

On the southern slope of the mountain another belt of porphyry is found, having the same course and strike as the one on the north side. Several very promising locations have been made, and are being worked vigorously. The most prominent, because large developments are being made, is called the Northern Light, owned by Hiram House & Co. The Northern Light extension is opening and looks well, and also the Virginia, owned by R. D. Howe, of Salt Lake City. Another very promising location is the Orphan Boy, owned by Charles Wilkes & Co.

The Oneida is opened by a shaft at the point of location to the depth of 120 feet, with drifts both ways on the vein about 30 feet, showing a well-defined vein of free gold ore from top to bottom. They have several openings on the vein south of their location point; they have also a tunnel near their northwestern boundary line, and have just made application for a patent. This mine is owned by Sweeney, Griffin and Nelson, all old miners and residents of the camp.

The Robinson and Austin mines are regarded as the mines from the fact that they have more ore in eight and more developments than any others in camp. Ore from 13 to 40 feet wide can be seen the entire length of the locations, and of a fine average grade. Knowing the value and being fully satisfied of the permanency of the supply of ore, the owners have decided to be conservative at the outset, and not to expend money too hastily, but wish everything done to be of permanent service. They are now putting up boarding houses for the men, and preparations are being made to erect two or more shaft houses over the different openings on the mines, so that developments can be made during the winter months. A patent has been applied for both the Robinson and Austin.

Next to the Austin is the Nabob group of mines, located at the head of Anderson gulch, called the Nabob, Peterson and Boss. These locations are being worked through the aid of a Mr. Byrum, of New York, a gentleman of considerable mining experience. Three shafts are being sunk on the different veins, showing a fine average grade of ore. I understand it is the intention of the owners to push developments all winter with a view of building a mill next spring.

WEEDS.—Prof. Gray has been led to conclude that self-fertilization is neither the cause, nor a perceptible cause of the prototency of the European plants which are weeds in North America. A cursory examination has brought him to a similar conclusion regarding the indigenous weeds of the Atlantic States—these herbs which, under new conditions, have propagated most abundantly and rapidly, and competed most successfully in the strife for the possession of fields that have taken the place of forests.

MECHANICAL PROGRESS.

Weldless Chains and Cables.

Chains and cables, says the *Mining Journal*, have hitherto been made of iron generally from round bars or rods, and bent into shape and each link welded, but Mr. W. Deakin, of Birmingham, has invented a process which consists firstly in making chains and cables from steel, homogeneous, or metals such as Bessemer, Siemens, or similar material; and, secondly, in constructing the said chains and cables in such a manner that the operation of welding is entirely avoided and dispensed with, thereby producing a perfectly weldless chain or cable from end to end.

This may be effected in various ways, as for instance, he can take a piece of a bar of the said metal formed to any convenient shape and design suitable to the multifarious and numerous purposes for which chains or cables are required, and which may be bent into form by any suitable appliances, and manipulated by such means as hammers, rolls, chains, cutters, punches, presses, stamps or dies, or their equivalents, and actuated by steam, hydraulic, or other convenient power, and by such means to admit of one link being lapped, doubled and looped through another and so on to the completion of the chain without welding of any kind. Or he may roll such metal into plates, plain or indented, of the desired thickness, and stamp or cut out blanks therefrom of the required shape and dimensions for forming such weldless links, to be afterwards made into a chain or cable according to his invention; or he may cast such links into the suitable form required for the purpose, and subject such links to the operation of hammering, stamping, or pressing into the finished form, the said process contributing very materially to the solidifying and improving of the metal under operation.

It is claimed that by this process the cables possess increased strength and greater durability, and are of less weight than the welded. Besides mathematical accuracy in the link is secured, and the strain equally distributed without a weak point of attack. The element of cheapness is also very great.

Carving Attachment for Lathes.

The last number of the *Scientific American* gives a description of a carving apparatus from the workshop of M. Arhey, of Paris, France. It is intended to be attached to common lathes for the purpose of grooving, channeling and ornamenting columns, balusters, table-legs and similar articles of irregular shape. The carving attachment is placed on a traveling carriage, and supported on an adjustable cylindrical standard, to which the balanced arms of the cutter shaft are pivoted, the latter being revolved by a pulley and belt connection with a traveling pulley of the cutter-actuating shaft. The cutter shaft is movable on its bearings by a lever handle, while the pulley is retained by a clutch connection with a fixed brace of the weighted arms, and it is raised or lowered by means of a curved arm and guide roller passing along the pattern of the form. When a table-leg or other object is held in position of rest in the lathe, the cutting tool passes longitudinally along the same, and works out in it a groove or channel. The dividing disk being turned for the distance of one subdivision after each channel is completed, the next channel is then produced by the return motion of the carriage. By turning the object slowly in the lathe, simultaneously with the revolving and traversing motion of the cutter, helicoidal channels or grooves are formed. For grooving conical parts the cutter shaft is guided along an inclined guide pattern, or its axis placed at an angle to the longitudinal axis of the lathe. The cutter adjusts itself to the shape of the object, and carves by its uniform forward motion, an ornamental groove of equal depth throughout the entire length. For the purpose of pearling or doing other ornamental carving, the cutting tool is guided to the work by a handle, while the object is turned in the regular manner by the dividing disk, so that the pearls may be formed at uniform distances.

The adjustability of the cylindrical standard, in connection with the balanced cutter shaft and handles, admits of the convenient and accurate handling of the carving attachment, so that a large variety of ornamental work may be accomplished on this machine quickly and economically.

CERAMIC POTTERY ART.—For 30 years British potters have looked with jealous eyes upon the rapid growth of the pottery interest in America. Pottery in the United States, as a practical investment and assured process, dates back to 1843; in 1852 it was regarded worthy of special consideration, but it is only 17 years ago that the art assumed an important aspect. Artistically viewed, England has the advantage of 300 years of experience, and the bulk of the trade of all the world. A curious fact in this connection, in view of the rivalry now existing between England and America, and one unknown to most potters, is that in 1632, about the time when the first chinaware was made in England, the principal clay used in its manufacture was obtained from America, being purchased from the Cherokee Indians of the Carolina, and was called by them *unaker*. This

material was used for 30 years, and only abandoned because of the great expense of transportation. At that time great fears were entertained in England lest America should be able to flood the world with a superior china, but the china clay beds at Cornwall arrested the impending danger. To-day, however, the ceramic pottery art as developed at Trenton, N. J., promises to cope successfully with the best goods of Staffordshire, England. Prof. Longfellow has pleasantly described the progress of this art in one of his recent poems.—*Ex.*

RAISING CREAM BY CENTRIFUGAL FORCE.—German inventors have for some time been attempting to accomplish the quick separation of cream in the fresh milk with the aid of centrifugal machines. As the result of their efforts, we may perhaps soon look for quite a revolution in dairy matters, since what now requires several hours may be as well done in one hour or less. The first attempts were far from successful; but by the latest improvement the cream is drawn off while the vessel containing it is still in rapid motion, instead of after stopping it, and waiting till the milk has become quiet. The apparatus is made with a capacity of either 100 or 200 quarts. After it has been revolving rapidly for 20 or 30 minutes, and while still in motion, a quantity of skim milk is allowed to flow in; as the vessel was already full before, the cream is crowded out, and escapes through an opening provided for the purpose. Thus from 80% to 90% of the cream may be obtained in this short space of time. The *New York Tribune* says that an American inventor has been recently working in the same direction, and somewhat on the same plan, and that with his apparatus he has so completely removed the cream in 15 minutes that when the skim milk was set aside for 24 hours hardly any cream was deposited, and that he made butter from the milk within an hour after it was drawn from the cow.

A SOLAR ENGINE.—If the various schemes for utilizing the waste forces of nature are only partially successful, a tremendous quantity of power will convert the desert places of the earth into gardens. Capt. Ericsson has been engaged for the past 15 years, it is said, perfecting his invention of a solar engine. If erected near the seaboard, where water is to be had, the new engine will, he claims, generate steam, and where water is not procurable atmospheric air may be made the medium for transmitting the solar energy to the motor. In recent experiments under a clear sun, the engine worked with perfect uniformity at a velocity of 200 revolutions per minute, and consumed only a part of the steam furnished. To obtain some idea of the future possibilities of this engine, says an exchange, it should be borne in mind that there is a rainless region extending from the northwest coast of Africa to Mongolia, 9,000 miles in length and nearly 1,000 miles wide. Estimating a width of one mile only to be employed, not less than 22,300,000 solar engines, each of 100 horse-power, could be kept in constant operation nine hours a day by utilizing that heat which is now wasted on the comparatively small areas of land extending along some of the water fronts of the sunburnt regions of the earth.

MARINE VELOCIPÈDE.—A curious machine for skimming over the surface of water has been devised by E. P. Harrington, a Detroit inventor. It has been shown by experiment to be a success, although the present machine is rather crude. It is proposed, however, to build it according to new designs, for practical use. This water velocipède will have hand levers, which will operate a compound crank to propel the wheel. The speed can be accelerated by a combined hand and tread force. The buoyancy will be obtained from two swans, upon the backs of which will rest the weight of the rider. The wheel will also have a buoyancy of many pounds. The whole affair, thus sustained, will be as safe as any water craft, and may be operated by either lady or gentleman. When arrangements have been completed, these marine velocipedes may come into general use on the water, and will be a novel adjunct to aquatic sports. The regattas will be incomplete without a marine velocipède race. The velocipède owned by Mr. Harrington has been ridden by his daughter with safety on a small body of water. The invention will be known as the Detroit marine velocipède.

FIRE EXTINGUISHER.—At the exhibition of applied science now in progress in the Palais de l'Industrie, Paris, Senor Barriolas exhibited a *mata-fuegos*, or fire extinguisher. It resembles the well-known *extincteur* in outward appearance. It is filled with water, to which is added a charge of bicarbonate of soda and some other ingredients; and a small cylinder, inside the large, is filled with a solution of tartaric acid, etc. When it is required to bring the appliance into action, communication is made between the acid and alkaline mixtures by opening a valve by means of a handle and screw, when carbonic acid gas is evolved, which by pressing on the surface of the water, causes it to issue in a jet of 50 feet, the extinguishing action of the water being of course aided by the carbonic acid. The tartaric acid does not corrode the metal as sulphuric acid does, nor does it injure wood-work, etc. A pile of logs impregnated with tar and petroleum, and another of tar barrels were set well alight, when one ordinary No. 3 appliance extinguished both in one and a quarter minutes.

SCIENTIFIC PROGRESS.

A Wonderful Lubricant.

Grease has been deprived of one of its constituents by Senor Unciti, which gives it many wonderful qualities, if we may judge from the experiments lately made at the present exhibition of applied science in Paris, France. The *Iron* says: Two open boilers, made of tinned sheet iron, were put upon two coke furnaces of equal intensity; but the bottom of one of the boilers was coated with the grease outside, so as to be in immediate contact with the flame, whereas the other was not so coated. The former began to give off steam in a quarter of an hour, and the latter not until half an hour had elapsed; whence it may be inferred that the grease increases the conductivity of the metal, so that with a given quantity of fuel more water is turned into steam. A brass lubricator, of cylindrical form, filled with the grease, was then plunged into the water in the coated boiler, and, almost immediately, minute particles of the lubricant began to issue from a small hole in one end, rise to the surface, and gradually spread themselves over it. This was to show the application to the interior of a steam boiler for preventing incrustations, three grammes (about $\frac{1}{12}$ drachms avoird.) being used for each horse-power. The grease is also carried along by the steam into the cylinders, rendering any other lubrication unnecessary. Notwithstanding the cooling effect produced by the lubricator, a large body in proportion, the water in the coated boiler bubbled violently in an hour from the time of its being placed in the fire, whereas the other, not coated, did not boil in an hour and a half, when the experiment was stopped. A portion of the grease was wiped off from the bottom of the coated boiler and thrown on to the fire, when it immediately flared and was consumed. The tin bottom was as bright as before, but that of the other boiler gave evidence of the action of the fire. This was to show, on a small scale, that boiler plates exposed to the action of the fire do not become burnt. And, indeed, this fact follows as a natural consequence of the other point established, viz.: the increased conductivity given to the plates. Those who witnessed the demonstration were most astonished to see that a stick dipped in the grease made marks on the hot sides of the boiler and furnace as distinct as lines with a drawing-pen, and which did not run together, as they would have done if made with ordinary grease. So far the experiments have been most conclusive, fully bearing out the official certificate of the Spanish government; and it will be interesting to watch the result of a continued application to steam boilers on the scale of actual practice.

FUSING METALS WITHOUT FIRE.—A remarkable discovery has been made by Jacob Reese, of Pittsburg, Pa. He says he is able to melt instantly a bar of cast-steel one inch in diameter—which cannot be fused in less than five minutes in the highest furnace heat attainable—simply by throwing against it a column of air having a velocity of 25,000 feet a minute. The instant the air touches the metal fusion takes place. He says further: "By furnace heat it requires many hours, and sometimes many days, to anneal metals. By a recent discovery which I have made, I can anneal bars of iron or steel at the rate of one foot per second, thus increasing the ductility of the metal 100%, without the use of other fuel than that contained in the metal itself. I simply unlock the occluded (latent) heat. It becomes sensible and enlarges the metal, and by the method of doing this the enlargement is made permanent, that is, it does not contract to its original limit."

ANTMAL RUBBER.—An insect which produces a species of india rubber has been recently discovered in the district of Yucatan, Central America, by an American explorer. It is called Neen, and belongs to the Coccus family; feeds on the mangrove tree, and swarms in these regions. It is of considerable size, yellowish brown in color, and emits a peculiar oily odor. The body of the insect contains a large proportion of grease, which is highly prized by the natives for applying to the skin on account of its medicinal properties. When exposed to great heat the lighter oils of the grease volatilize, leaving a tough wax behind which resembles shellac, and may be used for making varnish or lacquer. When burnt this wax produces a thick semi-fluid mass, like a solution of india rubber, and it is expected that this glutinous liquid will be very valuable for cement and waterproofing.

A RACE WITH THUMBS ON THEIR FEET.—Mr. Tremlett, the British Consul, at Saigon, in his report this year, mentions as a remarkable peculiarity of the natives of the country that they have the great toe of each foot separated from the others, like the thumb of the hand, and it can be used in much the same manner, though not to the same extent. This distinctive mark of an Annamite is not, however, usually seen in the vicinity of Saigon, but is now confined to the inhabitants of the more northern section of the empire, where the race has remained more distinct. This peculiarity is the meaning of the native name for the Annamite race; and that the name and peculiarity are of great antiquity is shown by the mention in Chinese annals 2300 B. C. as that (or those) of one of the "four barbarian" tribes that then formed the boundaries of the Chinese Empire.

THE CELLULOSE MARVEL.—A capital example of those numerous industrial revolutions of which we have spoken, and which are peculiarly characteristic of America, is furnished by the new article celluloid. Although it was invented nine or ten years ago (by two brothers named Hyatt), its perfect manufacture has been regularly in progress for only about five years, and is considered to be still in its infancy; yet immense quantities of the substance are produced; it is converted into a wonderful variety of forms, and new modes of applying it are discovered almost daily. This composition of tissue paper, camphor, and certain chemicals is already used for billiard balls, combs, backs of brushes, hand mirrors and other toilet articles, whip, cane and umbrella handles, every kind of harness trimmings, foot rules, chessmen, handles of knives and forks, penol cases, jewelry of all kinds, pocket-books, mouth-pieces for pipes, cigar-holders, musical instruments, doll heads, porcelain imitations, hat bands, neckties, optical goods, shoe tips and insoles, thimbles, emery wheels, shirt cuffs, collars, etc. Its use as a substitute for ivory has already exercised a world-wide effect upon the ivory industry, the falling off in the demand having been felt in the remotest regions of Africa. It has lately been introduced as a substitute for linen or paper in the making of shirt cuffs, collars, etc. It has the appearance of well-starched linen, is sufficiently light and flexible, does not wrinkle, is not affected by perspiration, and can be worn for months without injury. It becomes soiled much less readily than linen, and when dirty is quickly cleaned by the application of a little soap and water with a sponge or rag.

THE RUSSIAN THIRTY-TWO-INCH OBJECTIVE.

A contract, it is said, has been made by Alvan Clark & Sons, of Cambridgeport, Mass., with the Russian government, relative to the great objective for the Imperial Observatory at Pulkowa, for a great telescopic objective. The proposed glass is to be the largest in the world. The contract provides that the definition of the glass shall not be inferior to that of the telescope in the Naval Observatory in Washington, and that the amount of light shall be greater in proportion to the increased area of the objective, allowance being made for the absorption of light by the glass. The objective at Washington is 26 inches in diameter; the proposed glass is to be from 31½ to 32 inches in diameter, with a clear aperture of 30 inches. Three years and a half are allowed for its completion—two years to procure the rough disks, and 18 months for grinding, polishing, correcting, etc., with an extension of time, provided good and sufficient reasons are given for the failure to finish within the specified period. When finished the glass will be mounted in Hamburg. The cost of the glass alone will be \$32,000. The material for the glasses will probably be furnished by French manufacturers, the Clarks finding them the most trustworthy.

TRAVELING STONES.—Many of our readers have doubtless heard of the famous traveling stones of Australia. Similar curiosities have recently been found in Nevada, which are described as almost perfectly round, the majority of them as large as a walnut, and of an iron nature. When distributed about upon the floor, table, or other level surface, within two or three feet of each other, they immediately begin traveling toward a common center, and there lie huddled up in a hunch like a lot of eggs in a nest. A single stone, removed to a distance of three and a half feet, upon being released, at once started off, with wonderful and somewhat comical celerity, to join its fellows; taken away four or five feet, it remained motionless. They are found in a region that is comparatively level, and is nothing but bare rock. Scattered over this barren region are little basins, from a few feet to a rod or two in diameter, and it is in the bottom of those that the rolling stones are found. They are from the size of a pea to five or six inches in diameter. The cause of these stones rolling together is doubtless to be found in the material of which they are composed, which appears to be loadstone or magnetic iron ore.—*Virginia City Enterprise.*

CARBON IN COMETS.—It is generally believed that some compound of carbon exists in comets, and it has been assumed that the bright lines in the spectra of these bodies were due to that compound being in an incandescent state. G. J. Stoney has advanced another hypothesis. He suggests that the bright lines are caused by the light of the sun falling on the compound of carbon and rendering it visible in the same way that light renders the moon, the planets, and other opaque objects visible, the vapor of carbon being opaque to the particular rays which appear as bright lines in its spectrum.

CURRENTS OF AMPERE.—Ampere asked if the molecular currents of magnets are entirely created in the magnetic substance during magnetization, or if the magnetizing cause merely determines a circulation of currents pre-existing in the metals in their natural state. He inclined to the latter opinion. The author thinks that there is every reason to admit, with Ampere, that the particular currents pre-exist in the magnetic metals, and that the current of the battery merely determines the circulation and the direction.—*M. Treve, in Comptes Rendus.*

Mining Share Market.

The condition of the stock market the current week does not present any salient features upon which to hang the forlorn hope of a "boom." An astonishing feature is the fact that the good news of the rich strike in Sierra Nevada did not cause the market to respond, except in one instance, when a slight but sharp advance was made in Sierra Nevada and Union Con. Perhaps the heavy, dull condition of the market does not depend so much upon lack of confidence in reports as in the fact that there is no money circulating, or at least attainable for speculative purposes. Manipulators, like sponges, have taken in all the pecuniary moisture of investors and have left nothing but the dry-as-dust but never-full class of "agents," who find their occupation gone. Active mining has diverted considerable money into other channels for the present. Perhaps the approaching change in the government of the State prevents many from disposing of their surplus income in speculation. Whatever may be the cause, an effect exists, viz, a dull though steady market, which it seems impossible to stir up by anything less than a tremendous explosion of some, at present unknown, financial phenomena.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Martin White, Oct. 13th, \$4,210; Belle Isle, Oct. 20th, \$16,000; Leopard, Oct. 16th, \$5,900; Belle Isle, Oct. 20th, \$16,000; Alexander, Oct. 17th, \$7,290.85; Northern Belle, Oct. 18th, \$9,122; Bodie Con., Oct. 20th, \$30,500.

LATE MINERAL PATENTS ISSUED.—Patents have been issued for the following mining claims in California, to date: Amador county—Thomas Sorrocco, et al., Placer. Butte county—J. B. Hewitt, Placer; Thos. H. Dodson, et al., Placer, Cherubusco mining district; Wm. Armstrong, Bobbies Blue Ledge, Wyandotte mining district. Calaveras county—Thomas J. Sparks, et al., Placer, Stone Cabin Gravel, Chile Camp; Lawrence Sullivan, et al., Placer; James Gunter, et al., Placer, Washington Ranch district. El Dorado county—Jorgen Anderson, et al., Sailor Placer; Jas. A. Hancock, et al., Old Henderson and Fryer Placer. Inyo county—Virginia Con. M. Co., Golden Gate mine, Keystone Lode, Sister Lode and Mill Site, Virginia mine, West Virginia Lode. Los Angeles county—S. B. Caswell, et al., Towseley Petroleum Claim; Jonathan D. Dunlop, Dunlop's Blue Light mine. Nevada county—Vincent G. Bell, Slide Quartz mine. Placer county—Frank Smith, Canyon Creek Placer. Tuolumne county—Henry Williams, Gilles and Carrington Quartz Mine and Mill Site. Yuba county—W. M. Crane, et al., Placer. I. E. Brown, Placer.

JACKSON'S UNIVERSAL WRENCH.—Andrew Jackson, of this city, has recently patented, through the MINING AND SCIENTIFIC PRESS office, an improved universal wrench, consisting of a novel combination of a stationary and movable jaw, the moving ends of which are separated or closed in a line diagonal to the handle by means of a screw, which actuates a movable nut. The movable jaw is hinged to this nut, so as to open or close at will, and is kept closed by a spring. The tool is simple, easily and readily fitted to any nut, bolt or pipe, and has few parts to become broken or get out of order. The shape of the jaws is peculiar. The fixed jaw has a depression formed in its end with three faces, while the movable jaw has two faces and a projecting lip, which extends over the end of the fixed jaw, so as to rest upon it when closed. The outer end of this lip turns up, so that the jaw will be readily opened by simply pressing it against the nut or pipe. Mr. Jackson's address is 143 Fremont street, in this city.

COURTNEY challenges any sculler in England, for £200 a side, the race to come off at the beginning of 1880.

The number of troops in Austro-Hungary is 1,094,000, in France 1,815,000, and in Russia 2,393,000.

Ex-Governor STANFORD has arrived at New York.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

ALPINE.—**Isabelle Tunnel.**—*Monitor, Argus*, Oct. 20: The tunnel is in about 1,100 ft, and is progressing at the rate of from 8 to 10 ft per day. This is an enterprise of great magnitude, the tunnel being 8x9, with a prospective length of some 0,000 ft. It has excellent prospects of success.

AMADOR.—**Butte Basin.**—*Ledger*, Oct. 18: A large body of water was struck in this claim on Monday, bringing the underground operations to a temporary standstill. The flow of water was so great that in spite of the pumping facilities, capable of throwing 20 gallons every minute, the water gained so rapidly that inside of 24 hours it stood three ft deep in a tunnel 100 ft in length. Mining has been abandoned for a few days, to see if the water will not decrease so that the present pump can manage it. If not, a steam pump will be brought into requisition. It is believed that the extraordinary flow of water is an infallible sign that pay gravel is close at hand.

CONY.—The contract for grading the mill site was let last Monday to some contractors, but grading operations have not yet been commenced, nor will they be until next week. The contract for building the 40-stamp mill has not been let. The heavy timbers for the batteries are on the ground, and the work will soon be under full headway. The new steam hoisting works are expected to be started to-day (Saturday), which will speedily solve the question of draining the shaft. Retimbering the shaft has progressed to a depth of 140 ft, and it is thought that not more than 100 ft more will have to be retimbered.

MISCELLANEOUS.—S. H. Clark last year put up a stamp mill to work this cement mill with in his gravel claim near Gleta. The gravel has changed since then, and will admit of washing by hydraulic power. The mill has heretofore been changed so as to crush quartz, and 20 tons from a quartz mine in that vicinity are awaiting crushing.

EL DORADO.—The Placer company are now running 80 stamps by steam power, the water being brought out of the ditch. Several hands have been at work to-day retimbering the tunnel, so that in a day or two it will be all right, and water coming down the ditch.

NEW ROASTING WORKS.—*Dispatch*, Oct. 18: The new roasting works for ore, of Emmons & Co., recently erected near the Good Hope mine, was put into active operation last Saturday, and we are told that it gave perfect satisfaction to its constructors and owners. They claim that their process of extracting gold from ore will eventually work a complete revolution in the working of gold-bearing quartz.

FAIR PLAY MINE.—This mine is situated on San Doung creek, a short distance west of the Hathaway mine, and about one and a half miles from the road leading from Marysville to the Big Trees, and owned by Smith & Co., of San Francisco. The owners are now running a tunnel and have already reached a distance of over 300 ft with good ore all the way. The lead has been traced for several hundred feet. The owners estimate the ore at about \$16 per ton. The lead is from two to two and a half ft in width. A mill will be erected on this claim in a short time. Quite a number of men are at work already.

THE UNO CLAIM.—This claim is owned by Sylvester & Co., and is situated on the Dehning ranch in Nassau valley. The Doctor says he has sunk a shaft about 30 ft deep. The vein is about five ft in width, and he thinks it will pay about \$10 per ton. He has extracted some 35 tons, which he is at present unable to work for want of proper machinery.

ITEMS.—The Fletcher Bros. are running a tunnel in their claim on what is known as Dead Horse hill, with fair prospects. Many rich deposits of gold were found on this hill in early days, and perhaps many more will be found in the years to come. Some 10 or 12 men are now engaged in mining on the hill, and the work is doing very well. The Vanderbilt mine on Chapparral hill, near Chas. sons, is being worked day and night. Potter and McCauley are engaged in mining on what was formerly known as the Doc Hill mine. Their shaft is down perhaps about 20 ft. The vein in the bottom of the shaft is some five or six ft wide and looks well, and they were told that the richest part was not more than six or seven inches wide.

BOSTON MINE.—*Chronicle*, Oct. 18: The property in this gulch has been sold to a San Francisco company. We understand it to be the intention of the new proprietors to thoroughly prospect and develop the mine, and a force of hands has already been set at work. A tunnel is to be run into the hill several hundred feet, on the ledge, preliminary to more extensive developments. The company will erect underground works in the near future, the rock carrying gold and silver-bearing galena, and the work is being satisfactorily worked by the ordinary milling process. The Boston mine is a large, well-defined ledge, and it has been pretty extensively prospected with favorable results.

NEW WORKS IN CHAMFION.—A new shaft is to be sunk, work upon which is already commenced. The old shaft—some 500 ft in depth—is too crooked to work. New hoisting works, the most powerful description are being erected over the new shaft, and the work of sinking is being pushed as rapidly as possible.

INO.—*Monitor*, Oct. 18: Work is going on in the 1000 level, with following results for last week: Drift south, 300 level, run 18 ft; connection drift between No. 1 and 2 crosscuts, 300 level, 15 ft; north crosscut, 300 level, 15 ft, and under drain, 92 ft. Total length of drift south, 300 level, 310 ft; connection drift, 300 level, 15 ft; north crosscut, 300 level, 52 ft; north crosscut 1000 level, 130 ft; under drain, 370 ft. Connection drift and silver-bearing galena, and the work is being satisfactorily worked by the ordinary milling process. The Ino mine is a large, well-defined ledge, and it has been pretty extensively prospected with favorable results.

TIN PINCHOT MINE.—*The Independent* speaking of this gold mine, the property of Messrs. Kelley, Beyer & Miner, says: It is situated on the side of the Sierras about five miles northwest from Big Pine, and one mile above the placers from which so much coarse gold was taken some years ago. It is the old Black Warrior, which McMurray opened and run astras upon in '73-'74. It passed into the hands of the present owners—who are thoroughly experienced in the business of mining and prospecting—in June last, or at least they then began work upon it. The ledge is full three ft in width, bearing honeycombed and decomposed quartz which, assayed by Curt Ober, at Mammoth, carries \$480 in gold to the ton. The country around is seamed with large and small ledges, but so far none have been sufficiently opened to show their worth. The mine in question has been worked through an incline 45 ft wide, and shows very rich in gold in the croppings. They are also located in several other late locations in that district.

MONO.—**HOMER DISTRICT.**—*Mammoth City Herald*, Oct. 15: Among the lucky owners of locations in the Homer district, situated on Mill creek, are our fellow townsmen Frank Hutchinson, H. D. Bequette and Charles Ball, who, together with Jack Kohoe and Hitecock, the discoverers, have located in the Sovereign claim, a 20-ft lode, showing well in gold, and the Hawkeye, a late discovery. The latter ledge is 15 ft wide, and shows very rich in gold in the croppings. They are also located in several other late locations in that district.

REFORMATION DISTRICT.—In consequence of some informalities in locating this district a few weeks ago, it has been referred to the satisfaction of the miners of Tioga and Jordan districts. The boundaries are as follows: Commencing at the quarter section corner on the line between sections 15 and 16, in township 2, north range 25 east, Mt. Diablo meridian; running thence north to Castle Peak district; thence west along Virginia creek to the westerly line of Mono county; thence south along said line to the head of Lee Mining creek; thence east along said creek to the line of section post, and thence to the place of beginning.

NOONDAY.—*Bodie Chronicle*, Oct. 18: In going down with the shaft three ledges were cut, the first 60 or 70 ft from the surface. The second about 150 ft, the third about 250 ft. These ledges had their top west of the shaft, but dip east; and on the 300 level all east of the shaft. The ledge at 280 ft is again cut by an east crosscut 30 ft from the shaft. The ledge cut at 150 ft is again cut in the same east crosscut about 110 ft from the shaft, and is well defined and is five ft thick, of good milling ore. On the 200 level the ledge has been exposed in the Noonday and North Rock districts, and is of about \$50 ft, all this to near the surface is ready to be mined out. On the 300 level, drifts are being run on the vein north and south preparatory to excavating the ore. The main shaft has been sunk to this 412 level, and timbers are being put in for a station. The mill is progressing finely and will be ready to run about December 1st.

SOUTH BUTLER.—Drifting north on this ledge from vein No. 2 on the 350 level. The ledge is looking very favorable, being more than the width of the drift of a fair character of ore. It is the intention of the company to put in pumping machinery at an early day, when sinking will be resumed.

MCCLINTON.—The west crosscut has been driven this week 10 ft; total 133 ft. The ground has been somewhat harder. The north drift on Eslington ledge has been advanced 10 ft, and the ledge has been cut. The east crosscut from new shaft has made good progress, being now in 40 ft, and cutting several seams of quartz this week.

UNIVERSITY.—The new three-compartment shaft has attained a depth of 130 ft. The formation is iron-stained porphyry, filled with seams of clay and quartz. The shaft is 13 ft 9 inches long by 4 ft in width, and is well and substantially timbered by 8x8 square timber, and lagged with 2 inch plank. A new safety-slip has been made and will be put in and running next week.

BLACKHAWK.—Quartz and vein formation still improving as the shaft goes down. Crossed a five-inch vein in drift at bottom of Warren winze. It looks well but does not prospect as well as it should.

CALIFORNIA.—The new shaft is down 44 ft, an advance of six ft. Rock hard in the bottom. During the week a small house was erected over the shaft.

GOOSHAW.—With the exception of one boiler and the pump the pumping machinery is on the ground—some 17 tons having arrived—and all hands are busy getting ready to place it in position. Superintendent Buckley is in hopes of getting the new works running between the 1st and 5th of November.

SOUTH STANBARD.—Grading for the new pumping machinery will be finished to-night, and the laying of the foundation will be commenced on Monday. By the time the foundation is laid the machinery will be here and the work of putting it in position will be pushed energetically.

BOOKER.—The shaft is down 462 ft. This ground is working better this week. The Cornish pump raises 190,000 gallons of water every 24 hours. Superintendent Elsworth has contracted for 700 cords of wood to run the works the coming winter.

NEVADA.

SMALL MINES.—The Nevada City *Herald*, speaking of the receipts of bullion from small mines in that vicinity, says: Phil. Richards, of his banking establishment on Main street, is buying and shipping an average of from \$3,000 to \$4,000 worth of gold per week that comes from the small claims in the vicinity of Nevada. It is a good showing, considering that this is the dullest season in the year for the business, and there are two firms in the city in the same line of business. The large quartz mines are as a rule producing bigger amounts than ever before known in the history of the state.

INYO MINE.—*Transcript*, Oct. 18: The vein on the 700-ft level, 1,100 ft east of the main incline, has been recovered and bids fair from the indications to be a bonanza of no mean proportions. The main chute of ore is found between the 1000, 1100 and 1200 levels to be doubling back to the west in this place of a letter U. The vein averages 4 ft wide, and in some places is 9 ft thick at the depth of 1,120 ft. It is strong and lively and carries more and more free gold as it descends. It is evidently approaching a more compact ore body than any yet encountered. This chute of ore has produced already 10,000,000 for the Idaho and Eureka companies. The fact that there is now a new vein on the 700 and 800 levels east, with 1600 ft of virgin ground, and heavy development on the 1100 and 1200 levels, are pretty good proofs that the prospects of this mine were never better than now.

A GOOD CLEAN-UP.—A crushing of 164 tons of ore from Pare & Ragan's claim, on Deer creek, just made at the Deadwood mill, paid about \$10 per ton. There are 190 ft of drifts in the mine, and nearly enough ore in sight to keep the owners at work all winter.

SOAPSTONE MINE.—We learn from the Grass Valley *Union* that a mill has been immediately erected at the Stockbridge Soapstone quarry, near Colfax, to reduce the rock and save the sulphurates which contain both gold and silver. The reduction machinery to be used is one of Cooper & Cowles' plans and rollers, which is an improvement on the old style Chile mills, the man being broad and having a large grinding surface, and the wheels being geared in a manner to make them capable of much more reducing capacity than the old style mill. This machinery is now in process of manufacture at Sacramento, and in about two weeks will be set up in running order at the quarry, being driven by steam machinery which is already in place. The quarry has been opened to a width of from 50 to 60 ft, and a great deal of the rock contains sulphurates which by actual working process is found to pay \$5 per ton. As it is easy of drainage and can be reduced into small pieces, it is a fine material for the mill, and can be realized by the saving and working the sulphurates, as they also contain the gold, there being none found in the rock. The sulphurates will then probably be worked by the chlorination process.

LIVE YANKEE MINE.—*The Transcript* says the Live Yankee mine near Nevada has been purchased by John T. Bradley of the *Union*. This mine was worked over a year ago by Fred Jones, who put up temporary machinery and sunk a shaft 123 ft. Drifts were opened and various crushings of rock made that showed an average of \$34 per ton. The last crushing went over 340 per ton. The ledge is from 2 to 6 ft in width, and is heavy in gold-bearing sulphurates. Heavy pumping and hoisting machinery is to be erected on the mine, and a three-compartment perpendicular shaft sunk to the 300 level. The mine is very rich and promising. Messrs. Bradley and Jones are both old Grass Valley quartz miners of many years' experience in the business.

ROCKY BAR MINE.—*The Foothill Tidings* informs us that this mine is now working about 75 men and continues to look favorably. A recent crushing of 250 loads of rock yielded \$30 per load, not including sulphurates, and the work is now going through which looks as well. The drift to connect the old Chavanne shaft is close on to completion, and the drain drift from the New York Hill has only about 100 ft to run. This will enable the work to go on in winter with much less expense, draining off the surface-water through tunnel. We learn from some of the company later in the week that the drift between the new shaft and the old shaft is likely to show a ledge, and there are two distinct ledges in the mine, about 40 ft apart. As both are pay ledges, it would seem a happy disappointment. A cross-cut is being run to connect the two and drain the old shaft.

RICH QUARTZ.—*Grass Valley Union*, Oct. 21: A clean-up of 27 loads of quartz from the Judd & Casey claim, on Ophir creek, made at the Fred Jones' mill, gave a yield of \$80 per load. The Judd & Casey is being worked in a quiet way, but it never fails to produce good results

when the crushings are made. The shaft on the claim is 210 ft deep, and the hoisting done with a whim. The ledge in the drifts and stopes shows a general width of about 18 inches.

SACRAMENTO.

THE FOLSON "STRIKE."—A correspondent of the *Record-Union*, who did the work, gives the following particulars: On the 17th of July prospecting was commenced with a set of artesian well-boring tools, and was continued with several interruptions till the 25th of September, when the granite was reached. Numerous rock strata were perforated and several auriferous sand and clay veins found, reaching as deep as 30 to 42 ft and was composed of green, sandy clay, containing blue clay averaging five cents to the pan. This vein is 12 ft thick and lies above the low-water level of the American river. From 50 to 60 ft is a vein of fine quartz sand and gravel containing sulphurates assaying \$15 per ton. No gold of any consequence was found from this till a vein of blue clay at 102 ft was reached. This strata lies on the granite and is 10 ft thick, making the rock 112 ft from the surface. As the shaft was commenced where the soil had been washed away some 25 ft, the granite is 137 ft from the natural surface. In this clay gold in paying quantities was found, and at the bottom, or just on the granite, 32 cents was panned out of about 25 cubic inches of earth. This mode of prospecting is now, and, I believe, has never been attempted in California before. Gold was found on W. Owyatt's land in the Lisbon reclamation district by the same parties operating at Folson, but the position of the strata containing it was such as to prevent its being successfully worked. The results at Folson show this to be a very satisfactory way of prospecting, and, as it is far less expensive than any other means now employed, will prove of great advantage to the mining interests. Not only coarse gold, but also the very finest float gold was obtained, and mining men experienced themselves as perfectly satisfied that the prospecting was thoroughly done. The intention is to prospect a large claim on the bank of the American river, and if future results are as satisfactory as the present, to open up and work the mine. At present work is stopped in order to completely work up the data already obtained.

SIERRA.

ITEMS.—*Messenger*, Oct. 18: The Bonanza company are busily at work raising their shaft, which will be about 300 ft deep.

The Union mine, at Gibsonville, has recently found richer ground than it ever had before. The company is working vigorously.

The shaft sunk by Horace Taber for this Monitor company has reached bedrock, but nothing was found on the bedrock to warrant drifting. Gold in small quantities was found all the way down until within a few ft of the bottom.

TUOLUMNE.

CONFIDENCE MINE.—*Democrat*, Oct. 18: Work is progressing in the mine with favorable results. The ore now being crushed is from the five and eight hundred ft levels. This week another fine body of ore has been discovered in the mine; the last, we heard, was opened 12 ft, showing a high grade all the way. There is ore enough to last for years of a moderate paying quality. The past history of the mine is sufficient to warrant a belief in its great intrinsic value, as at periods high grades have been found and paid very largely.

NEVADA.

WASHOE DISTRICT.

ORIMA.—*Gold Hill News*, Oct. 22: Hardly vein is being followed on the 2100 level at the rate of two ft per day, and is still yielding milling ore; total length of the drift from crosscut No. 1, 123 ft. The joint Mexican crosscut west on the 2000 level is now 272 ft in length and in hard-blasting porphyry showing some water.

SIERRA NEVADA.—The drift south and west from the 2300 station of the incline is now 99 ft in ore, the face still in the mill, showing a fine body of ore. The face is in the hanging wall. The water is out of the incline to the 2400 level, which is being cleaned out preparatory to starting a crosscut on the level, which will be done in a day or two. The workings east on the 2200 level and from the foot of the east shaft are now in 170 ft, the face in hard-blasting porphyry.

UNION CON.—The drift south and west from the 2300 station of Sierra Nevada incline is now in 90 ft, and passing through ore of fair grade and milling quality, although not so rich as that next the hanging wall of the vein.

ALTA.—On the 1850 level the drifts north and south have both cut into quartz. These workings have been swung round so as to enter the ore vein diagonally, and they are carrying a fine prospect.

COX, INYERLAND.—The drift from the 2000 level is down 65 ft and the bottom is in a beautiful formation of quartz but of low grade. This winze will be continued to the 2300 level for the purpose of opening that up. The east crosscut, 2600 level, starting 125 ft north of the south winze is being prospected by the diamond drill. At a distance of 20 ft from the lateral drift a body of quartz which extended some 40 or 45 ft in width, and yielded assays from the drillings of from \$5 to \$55 was struck.

MEXICAN.—The joint Union crosscut west on the 2000 level is in a mixed formation of soft vein matter with streaks of clay and considerable quartz; total length, 215 ft. The joint Union winze from the 2000 level is in a formation similar to that in the crosscut only carrying more water; total depth, 145 ft.

COX, YUBA.—The drift south from the west crosscut, 550 level, is now 100 ft in length and passing through a vein formation of clay and quartz. The winze from the 1500 level has of late been penetrating low-grade ore; total depth, 40 ft. The raise from the 1650 level to meet this winze is up 70 ft, and a drift has been started toward the point of connection.

BATTLE MOUNTAIN DISTRICT.

COOL MINE.—*Messenger*, Oct. 18: We learn from Walter Dawe that the mine owned by him and Mr. John Ramdohr at Ocala, is proving to be among the best in the district. They have 40 ft of shaft and 150 ft of drift. The ledge, which they argue is a fine body of ore, is 15 ft in width, and yields assays from the drillings of from \$150 to \$175 per ton, and 20 tons that assays from \$40 to \$60 the ton.

BELMONT DISTRICT.

BELMONT.—The last official report from the *Courier* says: Our stope north is looking well and yielding the usual amount of pay ore. The drift started north from No. 2 raise under the ore was advanced 6 ft during the week, through a vein of quartz 5 ft thick, with 1 ft of same good milling ore.

OTLA.—Letter of September 26th says: During the past week the south drift from south drift winze No. 2 was advanced 10 ft. In it we have struck a wide vein of good ore and one that promises to yield a large quantity. An average assay of the vein has not yet been made, but an assay of \$286.32 has been had from a selected piece. The stope in south drift winze is looking well and yielding about 6 tons per day. At the mill we now have 180 tons of ore. If we had said we would start immediately, it would have been the same. If we will have it in a short time, when the mill will start. In a few days—as soon as lumber can be got—I propose starting drifting in the 200 level, and think that in 100 ft we will strike the continuation of the old ore body worked during 1875. If not, we will certainly strike the ore we are now at work upon. In running this strike we greatly facilitate the handling of the ore and reduce the expense.

COMO DISTRICT.

ITEMS.—*The Lyon Co. Times* says: Como is assuming the appearance of a prosperous mining camp. Twenty new buildings already up and more building. Black Sparret ore was struck in the bottom of the Eureka shaft last Wednesday evening, assays of which go up in the hundreds. This had the effect of making the owners of the claim more exacting than heretofore; and whereas they would gladly have accepted \$30,000 for it a week ago, they now ask \$50,000.

[CONTINUED ON PAGE 268.]

Homer Mining District, Mono County.

Another "treasure trove" has been added to those already existing in Mono county, California. This one is in the Mill Creek mountains, now known as the Homer mining district. In a descriptive article, the *Bodie News* cites Holy Writ to the effect that "there is much gold there; and the gold of that land is good." We opine that very few mining districts are supported upon Scriptural authority, hence this new district possesses unusual interest on that account, if on no other.

It says: Homer district is situated 22 miles southwest of Bodie, within Mono county. In going up Mill Creek canyon for the first three or four miles, the high grey granite mountains, on either side, present a forbidding barren aspect, and no one, to quote the language of our text, would expect to find "much gold there," and it is not strange that the energetic prospector should have been so many years in forcing his way over the rocks and up the canyon beyond these granite peaks, to the gold and silver-ribbed mountains above. On reaching a point five miles above the mouth of the canyon, the appearance of the country suddenly changes, the mountains presenting a reddish brown and soft yellow color, and on examination these mountains are found to be composed of immense alternating dykes, thousands of feet in width, of metamorphic and talcose slate and quartzite, with here and there a dyke of some eruptive rock, not yet classified, but which will probably be placed in the family of trachytes. To the practical eye of the prospector, and the trained mind of the scientist, these alternating formations at once suggest the presence of rich gold and silver-bearing veins, and the recent discoveries there have fully confirmed the theories of both.

Gold was discovered in March or April, 1879, by William D. Wasson, who located his family at a point in the canyon five miles and a half above where it debouches into Mono Lake valley, and soon after began prospecting. He discovered several veins, notably the Golden Girdle and Little Blue, both of which gave promise of great value when properly developed. On the 23d day of August Charles H. Nye (a relative of the late U. S. Senator, James W. Nye) and Lawrence L. Homer discovered and located the Nioma and Wasatch veins, the remarkable richness of which was the primary cause of the excitement concerning the district. O. J. Lundy and his partners in the saw-mill in the canyon, Messrs. Boomershire and Morton, and also James McDonald, made discoveries early in the summer, some of which have proven to be of great value.

Later discoveries worthy of particular note, include the Crevasse, Secret and Wonder by Nye and Homer, the May Lundy, Minnie Lundy, Dick Turpin and several other claims by Judge Owens and others, two or three ledges remarkably rich in free gold recently discovered by James McDonald and others, the Callamer and Golden Prince by A. F. Proctor & Co., and the Lucky Dan discovered a few days since by Daniel Olsen. Dozens of other ledges have been discovered in the district within the last two weeks, many of which show free gold on the croppings.

The Principal Mines

Of the district, so far as present developments show, are the Nioma, Wasatch, May Lundy, Dick Turpin, Crevasse and two of McDonald's discoveries, the names of which we cannot recall. Many others show free gold in abundance, but the district is young and so little has been done in the way of developing the mines that it would be hazardous to venture an opinion on the merits of all. The Nioma is perhaps the largest vein discovered in the district. In some places it crops out bold and high, and is estimated to have an average width of over 30 feet, but part of the ledge, especially the western side, is somewhat mixed with talcose slate. Four samples, taken from different places and across eight feet of the ledge where the quartz was unmined, gave an average assay value of \$183 per ton, chiefly gold of fine quality. The Wasatch lies six hundred feet east of, and parallel with the Nioma. It is a small ledge about two feet wide, but very rich, one streak about eight inches in width being literally salted and peppered by nature, with free sparkling gold. We have seen specimens from this mine which would not suffer by comparison with the richest pieces from the Bodie mines. The Crevasse, a large, fine looking vein very recently discovered, lies between the Wasatch and Nioma, and within the surface boundaries of the former. There have been no developments made as yet on this vein, but the croppings, where uncovered, give good assays in gold. The Lucky Dan, and the very rich claims recently discovered by McDonald, lie further south and over the summit of the high ridge, and are probably extensions on the Nioma and Wasatch belt. The May Lundy and Dick Turpin are near these claims and are very rich, the latter in the latter being chiefly silver. The Callamer and Golden Prince both show very rich gold croppings.

Numerous tunnel rights have been located in the district, under the Congressional mining law, the mountains being very steep and favorable to that system of opening the mines.

The town site have been surveyed and laid off in regular blocks, with wide streets. One in the valley, directly below the Nioma and Wasatch claims, is called Wasson, and the other,

a mile and a half below, on the land of Mr. J. O. Lundy, an old pioneer who is living there with his family, is called Lundy.

Few places in this mountainous mining country are naturally so accessible as these new camps. Different roads leading from Bodie, Bridgeport, Aurora, Benton and Mammoth all converge near the mouth of Mill Creek canyon, and thence there is a good natural wagon road to within one mile of Lundy. Old Uncle Dan Olsen, of Bodie, has already applied for a charter to construct a toll-road up the canyon to the mines, and has had a working survey made and mapped by competent engineers.

It is said that capital has already sought and taken large investments in the mines.

Globe District, Arizona.

It is asserted by a correspondent of the *Phoenix Herald* that there is no other portion of the Territory of Arizona which promises more in the way of actual production than the Globe district. It already has the reputation of a great mineral belt destined to add largely to the wealth of Arizona. Indeed its wealth-producing power cannot be fully understood as yet while so many of its mines are still undeveloped, and tested by assay only, and so few mills are in operation to produce the bullion that the mines are capable of furnishing. As the tourist goes through the mountains, in every direction from Globe City he finds the outcroppings of ledges varying from a few feet to a hundred feet in width. These ledges can readily be traced for miles, in many instances across ravines and over mountain tops, and show such a vast deposit of mineral wealth as is rarely seen.

Hitherto the facilities for milling have been inadequate, and are so still, if the owners of mines would work them for the legitimate purpose of producing money by actual toll. This is a lesson the miners of Arizona must sooner or later learn if the Territory is to ever become famous as a rich mineral region. Capitalists will not buy mines at anything like a fair valuation unless they have been shown by actual mill test to possess more than a mere speculative value.

Happily for the district, there is now a fair prospect that the mills will be able to furnish miners with facilities for testing the real value of their property by actual production. The Isabella mill, for instance, is now running on custom ore, and the results are such as to fill even the most doubtful with hope as to the future of the mines in this region. When the mill was first erected it was hastily constructed, and the results were anything but satisfactory. In the month of June, the mill, run under the present management, produced only 2,892 ounces of bullion. Major Sisson, the present Superintendent, not being satisfied with the result—not paying expenses in fact—began to reconstruct the mill so as to be worked more economically by automatic handling of the ore, and so increased the capacity of the mill that the results have given a new impulse to the mining interest of this locality. The month of July and nearly the whole of August were spent in this work of repairing, and during the last two weeks they have worked 90 tons of ore, producing 20,430 ounces of bullion. They guarantee to the owners of ore 80% of the assay value, and charge \$45 per ton for crushing. At present they are running but five stamps, but the company have in contemplation the putting in of as many more, thereby doubling the capacity of the mill at but very little additional expense.

The little mill is a marvelous success, and will solve the problem of the mining interest of this section. In addition to this there is a prospect of four other mills being erected soon. The Miama mill, recently burned, will probably be rebuilt at once. A mill to work the ore of the Mexican mine will also soon be erected. Also one at Richmond basin, where they are now digging the well and laying the foundation for the machinery. One or two others are spoken of, and steam hoisting works are being put up on the McCormick mine.

The daily production of wealth is, after all, the only safe standard of value, and this is now being realized. Messrs. Eaton and Bailey have just had worked in the Isabella mill, from the dump of the Rescue mine, 29 tons of ore. The result was 15,296 ounces of silver bullion of a quality from 850 to 950 fine, and worth, at the standard value, \$19,313. This bullion is now on its way to San Francisco, and will have the effect of attracting the attention of capitalists to the hidden wealth of Arizona.

Rich strikes have recently been made in several of the mines, and large bodies of ore have been uncovered. In the Southwest Alice mine, owned by Dr. Thatcher and Mr. Morehead, at a depth of 100 feet a large body of ore has been found which assays 360 ounces to the ton. A discovery of rich ore has been made in the Silver Era. In other mines there are equally promising openings.

CHARACENE.—Dr. Phipson has succeeded in obtaining from organic substances present in fresh water a new and interesting product which he has named "characene." It is a kind of camphor which gives to the algae in general, and to the waters in which they grow, that peculiar, marshy odor which has hitherto been thought to be one of the results of vegetable decomposition, but which really arises from a substance produced by certain plants while they are alive and vigorous. As yet few of the properties have been definitely ascertained.

Rich Strike in Mammoth.

The Lake (Mono Co.) *Mining Review* gives an account of another big strike in the Mammoth mine a few days ago. It appears that on night last week, W. J. Perks, the night foreman of the Mammoth mine, found some rich ore in a new crosscut, which was started the other day from the winze which has been sunk from what is known as the Bonanza tunnel. Specimens were brought from the tunnel to the office, and "all hands agreed—even the oldest miners—that nothing like it in the nature of gold quartz had ever been dug out of the earth. The specimens were not small pieces as big as walnuts, such as are usually shown, but huge chunks, some of them weighing as high as 10, 15 and 20 pounds, and one great boulder going even as high as 50 pounds. All were literally alive with gold. On every side gleamed huge 'epitaches,' some as big as peach leaves, while all over and through the porous looking rock stood a solid incrustation of frosty looking gold, closely bound up with yellowish, iron-stained quartz. The size of the lumps and their formation indicated plainly the approximate size of the vein from which they came, and showed that it was no narrow knife-blade streak.

It will be remembered that the rich gold strike of last spring was made in a crosscut started in the winze 60 feet from its mouth. The new crosscut in which this strike was made is 45 feet from its mouth, or 25 feet above the old one. The rich rock was broken into but a few feet from the mouth of the crosscut, and in quality it is far superior to the find of last spring. And what is better, as a miner informs us, 'there are lots of it there.' The locality of the new deposit and its comparative nearness to the old one proves conclusively that the rich streak is an unbroken one for at least 50 feet in depth. How much further it goes down will have to be proved by crosscuts below the one run last spring. As we all know, the winze is now 200 feet. So there are yet 140 feet of 'virgin' ground to be tested by means of crosscuts. Whether this will be done immediately we are unable to say."

GOLD DEPOSITS AT FOLSOM.—Nearly all the gold mined from the alluvial deposits in California has been found in beds of gravel deposited by running water, and so universally has this been the case, that miners do not expect to find gold in paying quantities unless the characteristic strata of gravel are found. The enterprise of Mr. W. H. Dolman, of Oakland, in prospecting for deep-gold deposits in the bed of what was once an inland sea has developed a very different and unlooked-for condition of these deposits. Instead of the boulder and gravel strata that were expected on the bedrock, only strata of sand and clay intermixed with the debris of marine shells were found, and while fine gold in paying quantities was passed through at different levels, as the boring progressed, it was invariably associated with sand or clay and not with gravel, while the coarser gold was found on the granite underlying all, and in such amount as to give a guarantee to the successful working of these deposits, which bid fair to be richer and more extensive than any mines heretofore discovered either in California or elsewhere. As we have before remarked, the town of Folsom—where these discoveries have been made—is situated on the shore of what was once a sea from 200 to 300 miles in width and many hundred in length. The primitive rock, either granite or slate, is intersected with veins of quartz, all of which contain gold either free or in the form of sulphurets. There is every evidence that the whole surface of the adjacent rocks has been disintegrated and washed into the sea to the extent of several hundred feet in height. While the action of the waves, breaking along the shore for perhaps thousands of years, has reduced this debris to the finest of sand and deposited the gold on the bedrock in the condition in which it has been discovered.—*Folsom Telegraph*.

REMARKABLE GANGUE.—The Placerville *Republican* in a late issue says: The first lode in the vicinity of Coloma which commands attention is the Sam Simms mine, one and a half miles southwest of the town. This is the most extraordinary mineralogical formation in California, and is the only one of the kind known in the State, and lies in the western part of the mineral belt. Though its total gold yield has never been made public, it is generally known to be large, while the expense involved in its extraction has been insignificant. The remarkable feature of this mine is that the gangue, for the most part, consists of a very rare and valuable metal, supposed to be vanadium or roeoeolite. Quite a deep interest is being excited by it among scientists, and two very experienced mineralogists are now engaged in a series of tests, to enable them to determine, critically, what the mineral is. Should it be found in quantity, and prove as valuable as is now believed, additional importance will thereby be given to this portion of the great zone.

A PRE-HISTORIC CLAM-BAKE.—In excavating for the Jacksonville (Fla.) water works, recently, there was found, 28 feet below the surface, an ancient clam-bake. In a bed about six feet by four in area, the clam and oyster shells, many with gaping mouths, were arranged as for a modern clam-bake, intermixed with hardened sand, charcoal and fragments of decayed wood.

El Dorado and other County Mines.

A full account of the mining industries of El Dorado Co., California, appears in a recent number of the *Republican*, from the pen of M. H. Bennett, being the conclusion of a series of articles on the subject. In the general summing up, Mr. Bennett says that all the facts demonstrate that in this county quartz mining is rapidly gaining in favor, while placer and gravel mines are being operated with fairly good returns. The future gold yield of the State may be confidently coupled with a thorough exposure and utilization of the many and extensive quartz ledges. The quartz and porphyritic ledges and dykes are almost numberless, and it is owing to their disintegration, by time and atmospheric causes, that all, or nearly all, the hill-slopes, ravines and creek-beds have afforded such large returns to the surface workers.

Progress, such as is being made in improved gold-saving apparatus, and advances in the science of metallurgy, are combining to render many mines that were but recently considered unremunerative greatly esteemed, and vast quantities of tailings, more or less permeated with both free gold and sulphurets, will at an early day be made to return as much or more of the precious metal than when first milled.

All along the auriferous belt are to be seen what are termed "prospect holes," ranging in depth from one to two hundred feet. These have been abandoned, in most part, owing to a lack of intelligence as to the formation, impatience for a quick return; or, as in many instances, when fully convinced of the merit of the property, lack of capital prevents the successful prosecution of the work.

It is a very significant fact in connection with mining operations extending through the counties of Calaveras, Tuolumne, Amador, El Dorado and Placer, that wherever "deep sinking" has been done, the results have been gratifying. Yet, to an unaccountable degree does the opinion prevail now and heretofore has, and especially in San Francisco, that the veins along this great belt do, to use the local term, "peter out." A most forcible evidence of the fallacy and ignorance prompting such a conclusion is afforded in the case of the Pacific mine, at Placerville. Parties from San Francisco and New York, professed mining experts in times past, assuming the conducting of work for which they were totally disqualified, were the mediums through which large sums of money were expended without satisfactory returns, simply because the investigations were not intelligently directed, and as a necessary sequence, the property was as often abandoned and pronounced as worthless. During the year 1878, the attention of some English capitalists was called to this property, and their experts came almost at once upon a large paying vein of ore, milling tests of which proved so gratifying as to lead to the purchase of the mine, which, owing to the disfavor in which it had been held, was sold at a nominal rate, a fractional part of its value. Every additional foot of depth attained under the present administration, reveals the rapidly increasing quantity and value of the ore.

Another striking instance is that of the Church-Union mine, on the same belt and about five miles south of the Pacific. Within the past six years, it, too, was abandoned as unprofitable, yet when placed under the management and supervision of capable men, its intrinsic value was thoroughly established, and a property that was not long since sold for taxes, has within the past few weeks sold for a quarter of a million.

The Gwin mine, in Calaveras, is now, while being worked on the 1400 level, paying much better than at any previous period, while the history of the mines in Amador is too well known to be stated. Suffice it to say, they are now yielding handsome returns at depths ranging from 1,200 to 2,000 feet.

Much may and should be said of the abundant and economic supplies of water that are at command for mining uses, and when compared as a motor for hoisting work and milling, affords a very great advantage over steam power, as regards the facility with which it can be attached and the simplicity of its management. If, however, steam power be deemed requisite as an auxiliary, wood for fuel can be obtained here, for years hence, at half or less than half the cost of it in any other important mining locality on the Pacific coast or interior; and when the time shall have arrived for using coal, the transportation cost of placing it in and along the mineral belt of El Dorado will prove insignificant as compared with that of taking it to any of the other mining counties.

THE METRIC SYSTEM.—The educational society for introducing the Metric system, the American Metric Bureau, has just published a new edition of the standard work on this subject by its President, F. A. P. Barnard, President of Columbia College, New York, which has heretofore been published in New York at \$3 per copy. This new edition contains three times the matter, and has been made the most complete work in the language, its index of 2,000 references making it really a metric cyclopædia. The society wish to scatter it widely through the country, as the best means of giving accurate information about the metric weights and measures of which so much has been ignorantly written. They offer it at \$1.50, or one-fifth the rate charged by the New York publishers for the original edition. If not found at the book stores it can be had of the society by mail at \$1.70. The address is Secretary Metric Bureau, 32 Hawley street, Boston.

Valuable Iron Mine.

The Oakland Times of October 17th informs us that a capitalist of Oakland has secured the title to a mammoth lodge or deposit of pure red hematite or sesquioxide of iron; a recent discovery, located near St. Helena, Napa county, within three miles of railroad and 60 miles from this city. The deposit is the largest of this class of ore ever discovered on this continent, the ledge or vein being more than a quarter of a mile in width, cropping out boldly on two mountains, separated by a deep canyon through which a stream of water flows, and the ore being exceedingly rich; thus making the discovery one of the most important to this coast that has been made since the discovery of the Comstock.
